VOLUME LXVIII.
Number 1.

SAN FRANCISCO, SATURDAY, JANUARY 6, 1894. 95594

Three Dollars per Annum.
SINGLE COPIES, 10 CENTS.

An Amador County Stamp Mill.

The illustrations on this page are typical views of mill and water ditches of a California mine, and are such as may be seen in any mining region. The location is near Amador City, Amador county, and the properties are the Mayflower and South Mayflower (formerly the Bunker Hill). The history of these properties is interesting. They have been great producers in the past, and it is gratifying to know that an effort is being made to place them again in the list of paying mines. After many years of active operation these properties in 1880 passed into the hands of the Spring Garden National Bank of Philadelphia. Several years since the bank failed and the properties went into the hands of the receiver. Operations stopped and the mines were allowed to fill with water. May 1, 1893, the mines were leased to Dr. Stephen H. Emmens, who has transferred them to the present owning company, the Mayflower Gold Mine, which in turn has granted a lease (with leave of purchase) of the Bunker Hill claim to the Chicago Gold Mining Syndicate. The Mayflower has already paid a dividend to the new company. Work on the South Mayflower is rapidly progressing.

The mill shown in the cut contains 40 stamps and 16 concentrators. It is run by a six-foot Knight wheel, supplied with water by means of a pipe from the water company's ditch. It is also provided with ample steam-power for use in the event of the water supply running short at any time. Having regard to the period of its erection, and to its enforced idleness for two years prior to the recent resumption of work, the buildings and machinery are in fair condition. Ten stamps have been put in repair and are running satisfactorily; and the work of repairing a second

A WATER-POWER DITCH IN AMADOR COUNTY.

battery of 10 stamps is under way. The remaining 20 stamps can be speedily made serviceable immediately the mining developments shall open up an adequate supply of ore. The chlorination works will be placed in condition for roasting and reduction.

The arrangements for handling the ore are good. The mineral is automatically dumped from the skip at the mouth of the shaft into cars which descend to the mill by a self-acting gravity incline and discharge into rock breakers. The ore is not handled from the time it leaves the mine until it passes away as tailings into the Rancheria creek. The assay of the tailings rarely goes higher than 50 cents per ton, thus showing a very high milling efficiency. At the point in the upper cut indicated by the cross, it is proposed to sink a new shaft on the Mayflower.

FORTY-STAMP MILL ON RANCHERIA CREEK, AMADOR COUNTY.

JOHN H. HOBART of Oakland is the inventor and patentee of a process of saving "flour" gold from slimes and whatever escapes a mill. The device has recently been in operation at the Harmony (gravel) mill, Nevada county, and is claimed to have saved not less than two ounces of amalgam per day, and in 20 days 47½ ounces. As described in the *Herald*, the device consists of a closed box about the size of a butter box, and is set up at an angle of about 45 degrees. The water bearing the slimes from the mill passes over a plate and into the box, which is divided into three compartments. It runs onto a plate which is bent at right angles and is covered with a screen; striking the plate at one edge and running down, thence back to the rear edge, thence to the bottom of the box; running onto the second screen, and finally the third. The bottom of the box is covered with plates. The box has a lid which fits tightly, and three plates are fastened to the lid so that when closed they hang in the water, and between the three compartments. These are intended to catch the flour gold floating on the surface of the water. The device is to be used also at the Champion quartz mine.

TABLE OF CONTENTS.

ILLUSTRATIONS.—A Water-Power Ditch in Amador County; Forty-Stamp Mill on Rancheria Creek, Amador County, 1. Bracket Plume and Trestle Miocene Company, 5. Boiler Tube Cutter, 8.
EDITORIALS.—An Amador County Stamp Mill; Miscellaneous, 1. Mineral Product of United States for 1892; Gold and Silver in 1893; Miscellaneous, 2. Important Mining Deal; The Quicksilver Outlook; Miscellaneous, 3. The Wilson Bill and Its Chances; Miscellaneous, 3-4.
MISCELLANEOUS.—Hydraulic Mining, Treatment of Ariferous Pyrites, 5. Ore Chlorination in Arizona; Placer Mining in Alaska, 6. Influence of Country Rock; The Kimberly Diamond Mines; The Laws of Optical Projection, 7. Slacks, 8. To Coin Silver Bullion, 4. **CORRESPONDENCE.**—Important to Alkali Land Owners; The Fire Hydraulic Mine, 6. American Mining Laws; The Deepest Gold Mine, 4.
SCIENTIFIC PROGRESS.—Gasification of Coals and Liquid Hydrocarbons; Discovery of the Telescope; Diamonds in a Meteorite; Light Intensity of Tints, 8.
MECHANICAL PROGRESS.—Boiler Tube Cutter; Amalgam Cement for Porcelain; Making Large Steam Pipes; Soldering Aluminum, 8. To Wash Carbon from Smoke; Fuel of Steamers, 9.
USEFUL INFORMATION.—Varnishing; Safety Elevator Device; Coke Sweating; A New London Bridge; Solidified Petroleum; To Strengthen Copper Pipe, 10.
ELECTRICITY.—Nikola Tesla; An Electric Light House, 10. Electricity in Agriculture; Dry Batteries in Telephone Exchanges in Germany; Mysterious Display in Texas, 11.
MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 13.
THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 15.

The Midwinter Fair was informally opened January 1st. It will probably be February 1st before the formal opening can take place.

The Debris Commission held a meeting January 2d. Licenses were issued to Joseph Davis, Manuel Mateos and Frank Barbero to work three small placer mines in Howard Creek, near Sierra City. The following mines were authorized to build dams: The Red Hill, Badger and Walker mines, near Ono, Shasta county; the Tannery mine, near Brownville, Yuba county; and the North Star and Green Mountain mines at Mokelumne Hill, Calaveras county. The Fifty-four Flat mine, near Volcano, Amador City, was authorized to submit a plan for a dam.

The determination of the problem of the amount of water to be used for irrigation in the West is the object of investigation now in progress at the geological survey. The scientists of the survey have completed a chart showing the "mean annual run-off in the streams of the United States." It was compiled under the direction of Geologist F. H. Nowell, and is the first map of its character ever made. It is the result of about fourteen years' study, though only since six years ago has the investigation been conducted on an extensive scale. During the past six years all large rivers in the country have been gauged by survey scientists.

The intimate relation between mining and agriculture has been conspicuously shown in Idaho and eastern Washington during the past year. The great Oeur d'Alene district has always depended upon the Palouse country for its produce, and it is a fact that never until this year have the farmers been able to supply the demand for fruit and vegetables, butter, eggs, etc. Now the farmers have no market for these things and their distress is great. Exactly the same experience has been undergone in California. When the hydraulic mines shut down, the farmers near the mines were, next to the miners, the greatest sufferers. There was no sufficient demand for their products. The want has not yet been cured.

MR. GEORGE E. MILLS, a California mining man, who has just returned from a several years' stay in the East, writes to the PRESS relative to the deplorable condition of the iron-mining industry in New York and Pennsylvania. Iron furnaces, rolling-mills, wrought-iron pipe mills, steel-converting mills, iron and coal mines, and nearly all the coke-furnaces, he says, are idle. Thousands of men are out of employment and know not where to go or which way to turn. "I have never," says Mr. Mills, "seen such idleness and dull times in this country." Mr. Mills has been at work on the machinery of the Melton gold mine, El Dorado county, which has been idle for four years, and which has suffered much from decay. It will soon be in running order.

Gold and Silver in 1893.

Reports of the mineral output of 1893 are already beginning to come in, Colorado, Idaho, Utah, and Nevada, having already been heard from in whole or in part. Of course there has been a heavy falling off in the silver output. The gold by-product has been seriously affected by the shutting down of the silver mines, but on the whole, it is probable that the increase in the gold mines proper will more than offset the difference. The first returns in are from Wells, Fargo & Co., from whom we have Idaho and Utah. A statement of Colorado's output has been prepared by a committee of business men.

Colorado.—The committee's report shows an increase in the gold production from \$3,636,217 in 1889 to \$5,539,021 for 1892, and calls attention to the great gold developments of the Cripple Creek region, where experts claim there is enough low-grade ore in sight to yield \$100,000,000. Leadville promises to rival Cripple Creek as a gold-producing camp, one mine yielding \$5000 per day. The gold output of Colorado in 1893 is estimated at \$8,300,000. Statistics are also given of the production of coal, coke, granite, petroleum and agricultural products, showing great prosperity and abundant resources.

Idaho.—The figures of Idaho's metal production for 1893 prepared by Alfred Oefs, cashier of the Boise City National Bank, for Wells, Fargo & Co., are as follows: Gold, \$1,645,000; silver, \$1,502,000; lead, \$775,000; total, \$3,922,000.

The figures last year were: Gold, \$1,790,000; silver, \$2,798,000; lead, \$2,475,000; total, \$7,063,000.

The decrease for the year is largely in the Oeur d'Alene where the mines have been closed down most of the time. The production of that section last year, under adverse conditions, was \$3,438,500, while for the year just closing it was only \$1,375,000. The closing of mines carrying silver mainly, with some gold, largely reduced the gold production, but it has been compensated for by the opening up of placer mining in new localities which had not heretofore been considered worth working.

Utah.—Wells, Fargo & Co.'s statement of the mineral product of Utah for 1893 shows a total of 94,072 ounces of fine gold, 7,107,503 ounces of fine silver, 1,062,467 pounds of copper and 70,097,079 pounds of unrefined lead.

The gold is reckoned at \$20 per ounce, and silver at 80.64 cents per ounce, copper at 6½ cents per pound and unrefined lead \$44 per ton, which makes the total export value \$7,926,601.28. Computing the gold and silver at mint value and the other metals at their value at the seaboard it would increase the value of the product to \$12,832,074.88.

In 1892 Utah produced metals as follows, according to Wells, Fargo & Co.'s statement: Gold, 38,182 ounces; silver, 8,969,656 ounces; unrefined lead, 91,117,107 ounces; copper, 1,822,616 pounds.

The Comstock.—The total ore product of the Comstock lode during the first three-quarters of the year 1893 was 46,365 tons. The bullion yield of this ore was \$683,162; total cost of extraction, transportation and reduction foot up \$955,606, according to the sworn statements of mine superintendents. The returns from the Savage include only the first quarter of 1893 and the Hale & Norcross has made no statement. The yield of the lode was divided as follows among the ore producing mines:

Consolidated California & Virginia ore yield, 14,347 tons; gross bullion product, \$261,895; cost of extraction, \$209,964; cost of reduction, \$73,522; total cost, \$276,018.

Savage.—(First quarter ended March 31) Ore yield, 4,672 tons; gross bullion product, \$73,163; cost of extraction, \$50,835; cost of reduction, \$28,035; total cost, \$78,871.

Kentuck.—Ore yield, 2,183 tons; gross bullion product, \$14,859; cost of extraction, \$11,439; cost of reduction, \$5,125; total cost, \$18,767.

Potosi.—Ore yield, 17,579 tons; gross bullion product, \$254,143; cost of extraction, \$157,890; cost of reduction, \$105,574; total cost, \$263,364.

Challenge.—Ore yield, 221 tons; gross bullion product, \$4,801; cost of extraction, \$6,522; cost of reduction, \$2,111; total cost, \$9,066.

Justice.—Ore yield, 1,229 tons; gross bullion product, \$15,029; cost of extraction, \$16,822; cost of reduction, \$7,680; total cost, \$24,482.

Crown Point.—Ore yield, 1,430 tons; gross bullion product, \$12,380; cost of extraction, \$35,693; cost of reduction, \$6,818; total cost, \$42,473.

Overman.—Ore yield, 813 tons; gross bullion product, \$9,063; cost of extraction, \$16,331; cost of reduction, \$4,068; total cost, \$20,567.

Confidence.—Ore yield, 268 tons; gross bullion product, \$3,173; cost of extraction, \$1,299; total cost, \$6,065.

Yellow Jacket.—Ore yield, 5,821 tons; gross bullion product, \$58,548; cost of extraction, \$85,333; cost of reduction, \$25,516; total cost, \$116,328.

Belcher.—Ore yield, 2,230 tons; gross bullion product, \$53,573; cost of extraction, \$30,765; cost of reduction, \$11,160; total cost, \$94,156.

Imperial.—Ore yield, 151 tons; gross bullion product, \$1,634; cost of extraction, \$1,323; cost of reduction, \$757; total cost, \$2,232.

When the statement of the last quarter is received it will probably swell the total bullion yield for the year 1893 to \$800,000, according to the estimate of the *Territorial Enterprise*. This is a marked falling off below the product of any year since 1884. Of the total bullion yield last year nearly \$300,000 was in gold. As a majority of

the other mining districts in Nevada are largely silver producing, and as the extraction of ore has been almost totally suspended since the depression in the price of bar silver, the entire bullion yield of the State for 1893 may not exceed \$3,000,000 against over \$6,000,000 for the year 1892.

Mineral Product of United States for 1892.

The report on the mining resources of the country, prepared by Chief Day of the division of mining statistics of the geological survey, and forwarded by telegraph from Washington January 31, shows that the high-water mark in mineral productions was reached in 1892, both in this and every other country. The total value of all the mineral products in that year was \$684,778,768. This is \$20,000,000 greater than for any previous year.

Among the large gains was \$77,130 tons pig iron, with an aggregate product of 9,157,000 tons, valued at \$131,161,039.

Gold showed a slight loss in the year's product, valued at \$33,000,000. There were 1,596,375 ounces.

The total production of silver was 58,000,000 ounces; coinage valuation, \$74,989,000. The amount is an increase of 877,130 ounces for the year. The increased valuation of the product for the year is \$2,821,054.

Copper gained 57,465,666 pounds, making an aggregate of 853,275,742 pounds, of the value of \$37,677,142.

Lead gained 10,856 tons, aggregating 213,262 tons, valued at \$17,061,950. There was a loss of 7000 tons in zinc. Aluminum was almost doubled. The year's product of zinc aggregated 87,260 tons, valued at \$8,027,920. Quicksilver, 27,993 flasks, valued at \$1,245,689. Tin from the mines of California, 160,000 pounds, and an aggregate for the year of 162,000 pounds, valued at \$32,400. Nickel, 92,252 pounds, valued at \$50,739. Aluminum, 359,885 pounds, valued at \$173,824.

Bituminous coal increased 3,000,000 tons, giving a total of 113,237,845 tons, valued at \$125,195,139. Petroleum is declining rapidly. In 1891 there were 54,000,000 barrels produced, but there were only 50,509,136, valued at \$26,034,196, in 1893.

Natural gas is also falling off, both in quantity and value. Its high-water mark was reached in 1888, when the product was valued at \$22,629,875.

Quantities and values of other non-metallic products produced during the year were as follows: Building stone, valued at \$48,706,625; lime, 65,000,000 barrels, valued at \$40,000,000; natural gas, valued at \$14,800,714; cement, 8,753,620 barrels, valued at \$7,152,750; salt, 11,698,890 barrels, valued at \$5,654,915; phosphate rock, 681,581 tons, valued at \$3,295,227; limestone for iron flux, 5,172,114 tons, valued at \$3,620,480; mineral waters, 21,876,604 gallons, valued at \$4,905,970; zinc white, 27,500 tons, valued at \$2,200,000; potter's clay, 420,000 tons, valued at \$1,000,000.

The total value of metallic minerals for the year is \$803,775,729; non-metallic, 871,003,109; unspecified minerals, \$10,000,000.

The report reviews in detail the use of aluminum, and states the principal use of the new metal in future will be in cooking utensils.

The use of the principal minerals in the first six months of last year was also reviewed, showing a great decline in the production, as anticipated from the general monetary depression.

The reader has, of course, not failed to observe that these figures are for 1892, not 1893. There can be no doubt that during the year just past, the mineral production of the United States has fallen off heavily. Silver, lead, copper, coal and iron will show a heavy falling off. There will probably be a decrease in quicksilver. Gold will hold its own, but will show an increase in California.

The announcement is made that J. W. Grace & Co. have arranged to put a line of tank steamers between this city and Peru for the purpose of conveying to this market the output of the Peruvian petroleum fields. The steamer Bawnmore has already been chartered for that purpose. It is said that the Bawnmore's cargo has already been sold to the San Francisco Gaslight Company for \$2.75 per barrel—the prevailing rate being \$3.50. The petroleum interest in California is large, the State standing fifth in the United States in rank of production. The output is extensively used for fuel purposes. The entrance into this market of the Peruvian product is of importance therefore to coal producers as well as petroleum. The high price of the former has to a considerable extent assisted the demand for the latter. The California wells have not in the past been troubled with direct competition, the high freight rates shutting the producers of the East and Colorado from this field. But if Grace & Co. are able to carry out their promises a very lively fight may be expected.

Important Mining Deal.

The Good Hope Consolidated Mining Company has just sold all its property in the Pinacate district, Riverside county, to Dudley Porter, John L. Hobson and Charles W. Morse, of Haverhill, Mass., for \$500,000—making altogether the largest transaction in California properties which has been recorded for some time. Colonel John M. S. Eagan of Georgetown, Col., manager of the Pay Rock mine near that city, is to have the management of the mines. One of the purchasers, Charles W. Morse, of Haverhill, Mass., who is in Riverside, says he will leave Sunday for San Francisco to purchase a stamp mill, mining tools, etc., to push the work. Colonel Eagan accompanies him, and will return to Colorado for his family and bring them to Riverside. The Good Hope mine was the first in the Pinacate district to reach a paying basis—and that it has paid well is evidenced by the sum realized for it and adjoining properties.

The peculiarities of the Pinacate district are such that they are worth noting in this connection. The veins of the Good Hope mine are in a dyke of light-colored biotite granite. It has considerable width on the surface—100 feet or more—but below ground some distance it is not over 12 feet. On the surface it is greatly decomposed and cut by numerous small veins, which are so scattered that they hardly pay for working. Below they unite to form larger veins, generally one on the foot and another nearer the hanging wall. The latter is more irregular, often running out at a small angle. The foot-wall, a dark, compact diorite, is very regular. The walls are separated by well-defined seams from the vein matter, the decomposed granite. Clay seams also separate the different veins. The foot-wall diorite forms the country rock indefinitely eastward. The hanging wall is a fine, dark brown mica schist. The quartz is generally friable, and the granite vein matter much decomposed. The quartz at a depth of 300 feet carried one-third of the gold in the sulphurets. A small amount of silver is also found. This vein is located for over a mile; direction a little east of north, dip 65° west. It is remarkable that there is no barren quartz; all the ore pays for working. In the lower workings the veins become more regular.

The sale of these mines is ample proof that there are good mines in California for sale. The recent offer of \$200,000 for the Nevada City mine is another. The purchase of the Rocky Bar and other Massachusetts Hill mines by James D. Hague is one more. The sale of the Alison Ranch, at a figure said to be large, is still another. The sale of the Hite mine, in Mariposa, is another. And so on the list might be multiplied indefinitely. The list of mines of what might be termed the second class (based on output) which has recently changed hands is very large. The organization of new mining companies—recorded in this paper from week to week—exceeds in number the record for many years. Some of these companies are organized to develop new, others to re-develop old properties. Their promoters seem to have had no unusual trouble in finding desirable properties. Where there is money to buy it will be found that there is a corresponding willingness to sell mines. If a purchaser thinks a figure exorbitant, he must act precisely as he would in any other transaction—refuse to buy. There are other properties. If an owner considers an offer too low—and he often does—he has the privilege of declining to sell. But, in the course of business, a common level is to be found. We believe that there is at this time no legitimate investment in the United States which offers such guaranties of profitable returns as a California gold mine. Capitalists appear to be coming to much the same conclusion.

THE De Lamar mines in Idaho have been operated steadily during the financial depression and have paid large dividends. The proportion of gold to silver produced is about 55 to 45, the former predominating. The ore, on account of the finely granulated condition and the softness generally of its porphyritic surroundings, submits readily to rapid crushing, three and a half to four tons per stamp being readily worked in 24 hours. The amount crushed per month is about 3500 tons. The amount shipped to smelters is valued at \$8000 to \$10,000 per month. The report of production by Captain Plummer, the manager, is: *Tons Crushed Dry.*—To March 31, 1892, 19,390; to March 31, 1893, 26,853.66; to Nov. 30, 1893, 22,387.85; total, 68,631.51. *Number of Ounces Pure Gold Produced.*—To March 31, 1892, 13,143.410; to March 31, 1893, 19,023.667; to Nov. 30, 1893, 16,581.424; total, 48,748.500. *Number of Ounces of Fine Silver Produced.*—To March 31, 1892, 317,112.59; to March 31, 1893, 487,137.74; to Nov. 30, 1893, 349,785.76; total, 1,154,036.09. The number of men employed in the mine in every department amounts to 175. The amount of dividends paid to date amounts to \$1,000,000. The amount of dividends paid for 1893 amounts to \$340,000.

The Quicksilver Outlook.

The executive committee of the California Quicksilver Mining Company has signed for another year the agreement that the Enreka Mining Company shall be its sole agent. Mr. George Staacke is the secretary of the company. There was no question raised at the meeting of the committee about shutting down the mines, but the advisability of lessening the production for some time will soon come up, and will probably be settled in the affirmative.

There has lately been an increased consumption of quicksilver among the electrical companies in the East, and a shipment of about 3000 flasks has been made to China, the first to that country for many years. In spite of this, however, the price of quicksilver has gone down, and several reasons have been given therefore.

The California mines produce as much quicksilver as can be used on the whole Pacific coast in the United States. The old Almaden mine in Spain produces 50,000 flasks a year; the Idria in Austria produces about 16,000 flasks, and this amount is increased from other mines in other countries. The European production has not materially increased, but the quicksilver mines on this coast are a unit in objecting to any reduction of the present duty of ten cents a pound.

"The export to foreign markets is about as usual," said a gentleman connected with Newhall & Co. to a *Call* reporter, "but the amount used in this country has shown considerable decrease since the closing of the silver mines in consequence of the anti-silver legislation. For one flask used in gold mining a great many were used in silver mining, and in the former case the large proportion can be saved, while in the latter but little was preserved. When silver stands at 68 cents an ounce, not one mine in twenty-five pays to work. That's the reason of the reduction of price, and at the present quotations I think only about five quicksilver mines could be worked with any profit."

The conditions which have brought about a disturbance in the local market, it is believed, will soon be removed, and matters will assume something like their former tone. The chief source of uneasiness on the part of quicksilver men is the prospective removal of the tariff duty of ten cents per pound (\$7.65 per flask). There is no reason why returning wheat vessels cannot bring from Spain or England to this port large quantities of quicksilver. The average difference in London and San Francisco prices of quicksilver is about \$7 per flask. It is certain that quicksilver can be brought to this city from London at 25 cents per flask, leaving importations from Spain out of the question. The inevitable consequence will be to bring San Francisco prices down to the level of London prices. From the standpoint of the consumer there will be no objection to this reduction; but from the producer there will be most serious opposition, for the plain reason that it means ruin to the industry in California. If the California mines are once shut down by reason of such competition, there is ample reason to expect that the price of quicksilver will rise, and the consumer will secure no lasting benefit. It will be raised because the Spanish mines are controlled by a great syndicate, which will be enabled to manipulate prices to suit its own convenience. It cannot be doubted that it will make the most of its opportunities.

A PRESS DISPATCH from Boise City says: An interesting fact developed that Idaho distanced all competitors at the World's Fair in the mining department in a smelter test after the fair closed. There was sharp rivalry over smelter returns from the ores sold. New Mexico led off with 50 ounces of silver and 10 per cent lead. Utah got \$300 for six tons, and Montana got \$800 for 16 tons. Then Idaho came in with \$1290 for 16 tons, the returns being 1.48 ounces gold per ton, 73.6 ounces silver and 49.47 per cent lead. The remaining States refused to try to match it. New South Wales admitted that their ore could not match it. Washington people gave their ore away, and Colorado did likewise. The 5200-pound chunk of Bunker Hill and Sullivan galena was purchased by the American Association of exhibitors, to be exhibited at Antwerp. Idaho has received 17 medals, awarded in the mining department.

It is not wise for prospectors and miners to become unduly excited over the fabulous reports which have come from the Goler and other districts in the Mojave desert. It is no doubt true that there is gold in these districts, and probably a good deal of it; but it is likewise true that the available placer territory is to a considerable extent appropriated. The disadvantages of existence in such a region should be considered by all who contemplate going there. It is dry, remote, difficult of access, and supplies are expensive. One who goes in must be prepared to undergo more or less hardship. There are, no doubt, some who will secure fine claims; the majority run good chances of coming out empty-handed.

Sliokens.

There is a movement on foot in Spokane to establish ore sampling works.

THE Last Chance mine, Hoopa valley, Humboldt county, is about to be sold to Richard Phelan, B. M. Lawrence, Albert Backman and J. A. Ryden.

THE Nevada City *Transcript* says the Good Hope and Lone Jack mines, at the Cabbage Patch, near Spenceville, were sold Saturday to J. V. Brooks of Kentucky, for \$60,000.

At an extraordinary general meeting of the Golden Gate Alluvial Syndicate, held at its offices in London, resolutions of reconstruction were unanimously confirmed. The company will henceforth be known as the "Golden Gate of California (Limited)."

THE Southern Cross Mining Company has been incorporated. Principal place of business, Oakland. Capital stock, \$750,000, with E. L. Ford and William Bentley, of Towles, Placer county, and E. W. Harlow, W. H. Mac and James H. Swift as directors.

It is reported authoritatively that the management and superintendency of the Baisley-Elkhorn mine at Baker City, Or., has been tendered by the directors of the Baisley-Elkhorn Mining Company to Mr. I. K. Farrel, manager of the Oregon Gold Mining Company at Cornucopia.

A LOCAL paper states that the "gold output of Colorado for 1893 is estimated at \$83,000,000, and in 1894 it will probably exceed this by \$20,000,000." All of which shows how easy it is to multiply figures. The total gold output in the United States for the past two years has not been so much.

THE Gold Bar Mining Company, at Vanderbilt, has been incorporated under the name of the Vanderbilt Mining and Milling Company. The incorporators are J. K. Patton, Anna M. Taggart, William Chambers, H. C. Dillon and S. F. Godbe. The capital stock, paid in, is one million dollars.

TEN FEET of shipping ore that runs 97 ounces in silver and 79 per cent lead has been struck at Ainsworth in the Slocan district. The find was made in crosscutting on the joint tunnel of the Little Donald and Little Phil. It is one of the most valuable discoveries in the northern mining country for a long time past.

RETURNING prospectors from South Africa report that in Mashonaland their pursuit is so hampered by undesirable conditions as to make it unprofitable. It is necessary to obtain the permission of the British South African Company before prospecting can be undertaken, and then, if successful, heavy royalties must be paid.

At the rate at which mining locations are being filed in this county, one would think that the mines would soon be encroaching upon the orchards, and these two industries become rivals for the possession of the land, says the San Jacinto (Riverside county) *Register*. Fortunately the two have not yet come into collision, and as the mere matter of unoccupied land has little to do with the progress of either of them, they are not likely to interfere with each other.

THE Silver Peak Mining Company, recently organized in this city, has purchased 20 locations in the Silver Peak district, Esmeralda county, Nev. The plans of the incorporation include the construction of a 150-stamp mill which it is expected to have in running order about the middle of next July. The ore in Silver Peak district is exclusively gold-bearing and there are numerous locations there being developed by miners on a small scale, who receive a good return for their labor.

E. J. POWELL, who has invented a process of saving gold from base ore, says the *Placer Republican*, has just constructed a machine designed after his system, and will give it a trial in a few days at one of the Ophir mills. He will try it on ore from the Gold Blossom mine, and if it proves a success Mr. Powell's fortune will be made. Those who have examined the model express great faith in its underlying principle, and the trial will be watched with interest.

A DISPATCH from Washington says the Geological Survey, in its work of publishing topographic and geologic maps of the entire country, has recently finished a number of different parts of California. With the maps is given much in the way of description that will be of inestimable value to those engaged in mining industries. The whole State of California has not yet been completed, but it is stated that most of the maps, particularly those relating to mines and mining, have been issued.

A SAN FRANCISCO paper of last Friday (Dec. 22) contained a long and startling account of an outbreak by the Hnachu Indians at San Carlos, Ariz. Many persons were reported killed and horrors committed. James M. Caw and E. S. Irwin, two mining men, have just returned from that part of Arizona, and they pronounce the statements false from beginning to end. There was no outbreak or expectation of outbreak. Such reports are designed to hurt a Territory as orderly as any in the West, and ought not to be printed unless they are known to be reliable.

IT TRANSPIRES that E. W. Fleming, who went to the World's Fair in the interest of the Idaho opal fields, worked something of a swindle. He agreed to send the people opals for a small sum to cover the cost of cutting, the charge being \$2. The stones were sent C. O. D. and he disappeared soon after the fair closed, and from a multitude of letters since received it appears that he sent bogus opals to a great many people. It is learned that he was recognized by the World's Fair people from California as E. M. Pennington, wanted in this State for swindling farmers by selling them common cactus plants for what he claimed to be hedge cactos. He went to Idaho in 1891, working a cactus scheme of some kind.

THE long and serious war dispute between the managers and miners at Northfield colliery, Nansaimo, B. C., has at last been adjusted, the men agreeing to accept a reduction equal to 15½ per cent, and the management making slight concessions with regard to handling dirt. It will be remembered that a strike occurred some months since, and that the miners agreed to return to work under a provisional arrangement until January 1st. The miners favored a settlement by arbitration, and the other day sent a committee to the management to notify them to that effect. The superintendent was unwilling to arbitrate, and for a time it appeared as if the men would decide in favor of a general strike. Finally cooler counsel prevailed, and a committee was appointed to again wait upon the superintendent and endeavor to arrange better terms.

The Wilson Bill and Its Chances.

It is announced from Washington that the Wilson bill is certain to pass both houses with no material changes—none at all affecting the general policy of the bill. It is possible, it is said, that some slight concessions to local interests will be made in committee, but no amendment will be suffered on the floor of either house. It is designed to railroad the measure through in exactly the same manner as the McKinley bill.

Of course the main fight will be in the Senate, where the Democratic majority is not so great as in the House. It is unfortunate for several of the great interests of the West—notably silver, lead and lumber—that three of its States—Washington, Montana and Wyoming—have each only one Senator. It may be assumed that they would make a strong fight against those features of the bill placing lumber on the free list and reducing the lead duty. As it is, the issue in the Senate is somewhat uncertain, notwithstanding the confident declaration that the bill will pass. The Democratic majority is not large, and there is some hope that several of the Southern Senators whose State interests are vitally affected, will vote against the measure.

The Western representatives in the Senate will of course oppose the measure, because their State interests are concerned, and for the no less important reason that all, with one exception, belong to parties different from that in power. From the mining States there is just one Democrat—White of California—and he will probably go with his party. It may be admitted that the chances of passage of the bill seem better than the chances of its defeat; but for all that the lead-silver miners and the lumbermen do not propose to be idle. The issue is of the most momentous consequence to them, and they propose to use every possible effort in their own behalf.

To Coin Silver Bullion.

Representative Oates of Alabama has introduced the following important bill to provide for the coinage of silver bullion now owned by the United States:

SECTION 1.—All silver bullion now owned by the United States shall be coined as speedily as practicable into standard silver dollars of the weight and fineness as now prescribed by law, which shall be legal tender in payment for all debts, public and private; *provided*, one-seventh part of said bullion may be coined into half dollars, quarter dollars and dimes in proportion directed by the Secretary of the Treasury and to contain the amounts of pure silver and alloy as now prescribed by law for such coinage.

Sec. 2. The Secretary of the Treasury shall set apart \$40,000,000, coined as aforesaid, for the redemption of notes issued by the Treasury and paid out for the purchase of silver bullion in the manner provided in the act of July 14, 1890, and whenever said sum is reduced below \$40,000,000 by the redemption of said notes the Secretary shall, from any other silver dollars in the Treasury not otherwise appropriated, add to the said sum so as to keep it up to the \$40,000,000, until the aggregate amount of said notes outstanding is reduced below that sum, and then the Secretary shall keep in the Treasury for redemption an amount of silver dollars equal to the amount of notes outstanding, until all are redeemed; *provided*, the Secretary may re-issue any of said notes when redeemed, as provided in the act of July 14, 1890.

Sec. 3. Any contract hereafter made by the Government of the United States, or between corporations, or between a corporation and a person or persons, or between private persons, which is by its terms or law payable in dollars or dollars and cents, may be paid at its maturity or thereafter in any lawful coin of the United States.

ADVICES from Pioche, Nev., are that Samuel T. Godbe has sold to Denver people the Monitor and Jim Crow properties, in Ferguson district, for \$450,000. The PRESS of December 9 contained an account of the transaction by which Mr. Godbe secured a bond on the mines. By its terms D. A. Reeves, A. C. Ellis and Frank Wilson parted with the Monitor, Monitor Dump, west half of the Cliff, the Princess, seven-eighths of the Lucky Bar and three-fourths of the Millionaire claims—on a basis of \$300,000, it is said. Messrs. Nesbitt Bros. and Mrs. J. McFadden list seven-eighths of the Jim Crow claim on a reported basis of \$150,000. The value of the properties is undoubted, though the real consideration may not be as great as reported. They lie on the proposed extension of the Nevada Southern. It is confidently stated that their transfer to people able to work them means that Ferguson district shall be one of the important mining districts of the coast.

FOLLOWING are officers of the Academy of Sciences for the ensuing year: Dr. H. W. Harkness, president; Dr. H. H. Behr, vice-president; J. C. Cooper, second vice-president; George A. Moore, corresponding secretary; Chas. G. Yale, recording secretary; L. H. Foote, treasurer; Carlos Troyer, librarian; J. Z. Davis, director of museum; W. C. Burnett, Charles F. Crocker, D. E. Hayes, E. J. Molera, George C. Perkins, Adolph Sutro, John Taylor, trustees. At the annual meeting, at which 20 members were present, the officers presented their annual reports. The report of the treasurer, General Foote, showed that the receipts were \$28,921.54, and the disbursements \$18,451.62, the gain for the year being \$10,470.02. The society received from rents during the year \$26,341.75.

American Mining Laws.

A REVIEW OF MR. RICKETT'S ARTICLE IN THE ELEVENTH STATE MINERALOGIST'S REPORT.

By Samuel Butler Jr.

One of the noteworthy features of the State Mineralogist's report, recently issued, is a "Dissertation Upon the Origin, Development and Establishment of American Mining Law." The author of this finely written and highly interesting treatise is A. H. Ricketts, Esq., one of the most prominent members of the San Francisco bar. It is a masterly exposition of the mining laws of this country, and they are discussed with a view of making them particularly interesting to the miners of this State. It proves conclusively that the author is thoroughly conversant with the important subject which he so ably discusses. We doubt if there is to-day extant a more explicit interpretation of our mining laws in so brief a form. It is something that those interested in the development of our mines have sadly needed; and the manner in which the subject is presented will be highly appreciated by every one fortunate enough to secure a copy of the State Mineralogist's report. As the writer tersely remarks in a brief introduction: "The aptitude of the American people for such achievement, the history of its great growth should be interesting as well to the student of law as to the miner whose welfare is dependent upon its due administration." Presented to the miners of California in such a concise way, it will be instrumental in saving them much trouble and expense when they find themselves engaged in legal difficulties. While we do not contend that such difficulties can be adjusted through this source, it is very evident that it will materially assist the litigant in pointing out the course he should pursue. To quote the author again: "Experience in mining litigation has enforced upon him the consciousness of liability to mistake, and that forecast can never equal the result of past experience." He has sought to present such an epitome (and it assumes to be nothing more) of American mining law as will be of practical benefit to those engaged in mining pursuits. For this reason alone it should be read and appreciated by every miner.

The question is discussed from four different standpoints: (1) The customs and regulations of the miners themselves; (2) State and Federal legislation and Federal treaties; (3) Spanish and Mexican law; (4) Judicial decisions.

Dilating on the early customs of the miners in this State, the author says: "In the days of early mining in California and elsewhere, from the very necessity of the circumstances in which the miners found themselves, customs grew up which soon became a guide for all, or in mass meetings regulations were adopted concerning mining rights, and rules as to the working of them, which had the force of law in the locations where adopted, and constitute the American common law on mining for precious metals."

It is very evident from the foregoing that at the time of the discovery of gold in California the laws pertaining to mining were very crude indeed, and were not particularly adapted to the system of mining then being introduced into this State. This condition necessitated the adoption of a system more favorable to the manner of mining in vogue at that time. Meetings were held in different localities, rules and regulations were introduced and adopted which eventually became the "common mining law" of this State. In speaking of these regulations and customs of the miners, Senator Stewart, the author of the Act of 1866, which was the first measure of importance to the mining industry introduced in the halls of legislation, remarks: "The Legislature of California had wisely declared that the rules and regulations of miners should be received in all controversies respecting mining claims, and when not in conflict with the constitution or laws of the State, or of the United States, should govern their determination; and a series of wise judicial decisions has molded these regulations and customs into a comprehensive system of common law, embracing not only mining law, properly speaking, but also regulating the use of water for mining purposes. The miner's law," he said, "was a part of the miner's nature; he made it, he trusted it, he obeyed it." And Senator Stewart was thoroughly competent to discuss this question in such a manner, for he was once engaged in mining for "precious metals" in this county in the very early days, and it is not unreasonable to suppose that he took some active part in establishing the "regulations and customs" of which he so eloquently spoke.

In the year of 1866 Congress passed the first measure which had for its object the creation and establishment of a system of Federal mining law. Prior to this time there had been legislation of a sporadic and unimportant nature pertaining to mining lands in different States. But such legislation was wholly inadequate to contend with the new and perplexing conditions; and the Stewart Act was offered as a remedy. Referring to this Act the writer says: "It marked a new era in the development of the American

legislation; and yet, it is a singular fact to relate, in passing that in its title, mines are not mentioned, nor the purpose of the Act disclosed." It reads: An Act granting the right of way to ditch and canal-owners over the public lands, and for other purposes. Continuing on this subject he remarks that "the miners of California and the States and Territories adjacent thereto, have but a very inadequate idea of the imminent peril in which the pursuit in which they are engaged, was placed at the commencement of the Thirty-ninth Congress. There was a strong disposition in Congress, and the East generally, to make such a disposition of the mines as would pay the national debt. The idea of relieving the nation of the payment of the enormous taxes which the war had saddled upon them by the sale of the mines of the far distant Pacific Slope, about which few people to-day have any knowledge whatever, was the most popular that was perhaps ever started. Compelling other people to liquidate your obligations, has been in all ages and all nations a highly comfortable and popular proceeding."

If either of the bills originally introduced had been passed, the Pacific States and Territories would have received a blow which time itself could not efface. The Government could only have receded from the anomalous position it was about to take after the most irreparable and widespread damage had been done. While we cannot perceive the legality of such action on the part of the Government, still, should the purposes of the Government be carried out as originally intended, the consequences would be appalling to contemplate. We hesitate to think of the results of such ill-advised action. Instead of being the happy possessors of a young, stalwart and ambitious State such as now graces the western extremity of this great continent, the brightest gem in the diadem of America, with a capacity of producing almost everything susceptible to growth, surrounded by beautiful and well-developed towns and cities whose fame has reached the "utmost parts of the earth," we might have retired in solitude and contemplated a dreary, desolate waste, destitute of everything grand and noble which now adorns the work of nature in sunny California. But through the strenuous efforts of Senator Stewart, this calamity was happily averted, and to-day we are credited with having added, through our mines, to the circulating medium of the country the magnificent sum of \$1,300,000,000. Where is there a like area in the world with such a capacity for producing gold?

There are many other points of interest in Mr. Ricketts' treatise which are worthy of discussion, but space forbids the attempt. Suffice it to say that I have been informed by the State Mineralogist that the treatise has been published in pamphlet form, and I hope it will obtain a wide circulation throughout the mining regions. It is worthy of careful perusal by every miner, and will prove invaluable to all interested in that industry. The State Mineralogist is to be congratulated on the acquisition of such a valuable article and the author for the production of such a lucid and elaborate interpretation of our mining laws.

Grass Valley, Jan. 1, 1894. SAMUEL BUTLER, JR.

The Deepest Gold Mine.

TO THE EDITOR:—In an interesting account of Grass Valley, appearing in your issue of Dec. 23, the Idaho mine is stated to be "the deepest gold mine in the world." This statement is often made in California, but it is not correct. The shaft of the Idaho mine is 2182 feet in vertical depth and 3050 feet deep on the vein. At Bendigo, in the colony of Victoria, Australia, there are at the present time twenty-five shafts over two thousand feet deep, and six over 2500 feet, namely: New Chum and Victoria, 2662 feet; Lazarus, 2598 feet; New Chum Consolidated, 2582 feet; Carlisle, 2510 feet; Victory and Pandora, 2515 feet; "180", 2860 feet. In some of the above-mentioned mines sinking is in progress, and additional depth has been gained. The Hundred and Eighty, or "180" mine, the private property of Mr. Geo. Lansell, is the deepest gold mine in the world. All the shafts at Bendigo are vertical. The deepest gold mine in Colorado is the California, in Gilpin county, which is 2290 feet on the vein and 2090 feet vertical.

Denver, Colo., Dec. 27, 1893. T. A. RICKARD.

THE PRESS contains this week a review of Mr. A. H. Ricketts' article on American Mining Law, in the Eleventh State Mineralogist's Report, by Samuel Butler, Esq., of Grass Valley. Mr. Butler is a working miner, and his opinion of the value to miners of the Ricketts paper is entitled to be considered a reflection of the views of miners generally. Mr. Butler has given much attention to mining matters in Nevada county, and in California generally, and it is likely that he will in future be a frequent contributor to the columns of the PRESS. He is able to express himself clearly and intelligently, and his communications are certain always to contain much that is worthy of consideration.

Hydraulic Mining.*

A REVIEW OF THE INDUSTRY BY DR. HENRY DEGROOT.

In Eight Parts—Part II.

Prerequisites to Success.—In making choice of a hydraulic property three principal things are to be taken into consideration. First—the percentage of gold contained in the material to be utilized, of which there must seem enough to warrant the expenditure required for the purchase, equipment and cost of working the property, interest on capital invested included. Second—water in ample supply, easily available and capable of being delivered in the washing pit under a head that will insure effective piping; and, third—sufficient fall or “dmp” immediately below the mine to prevent the tailings accumulating to a troublesome extent, unless, as sometimes happens, the latter can be dropped directly into a stream large and swift enough to carry them away. The above conditions being present, a hydraulic enterprise, well conducted, may be expected always to reach a fair measure of success. If there is timber on or near the mine suitable for making sluice blocks, sluices, flumes, trestles, etc.; if it is accessible for teams, not far from railroad or river transportation, and the winter climate is not so rigorous as to form much ice or otherwise interfere with outdoor operations—these, though secondary, are by no means unimportant elements of success.

Prospecting the Deposits.—In making tests of the auriferous gravel to be examined, samples should be taken from every accessible part of it; from open cuts, if any there are

grade falls much below six cents per cubic yard, this being about the average yield of the gravel handled on the Pacific Coast. If the reports on the Ecuador gold fields, alluded to, may be credited, the deposits there will yield at the rate of 40 cents per cubic yard, but these reports remain to be substantiated by actual workings; moreover, the gravel banks of that country are by no means so deep as most of those in California.

Opening Up and Equipping the Mine.—A hydraulic property having been acquired and prospected in accordance with the rules above prescribed and proving satisfactory, the next thing to be done is the construction of a ditch for bringing in water for washing purposes. The cost of this ditch will, of course, vary according to size, length, natural obstacles encountered and difficulties to be overcome, these various hindrances, owing to the rugged character of the country traversed by these artificial waterways, being many and formidable.

In the endeavor to surmount these impediments, recourse has been had to structures of various kinds, such as flumes, trestles, open cuts, tunnels, iron pipes, etc., the flume in one instance, where was presented no other practicable way for carrying forward the water, having been bracketed to the face of a towering cliff, after the manner shown in the cut.

Nothing so bold or original as this has, perhaps, ever before been executed or attempted in the department of engineering, whether for the transmission of water or other purpose.

In selecting and locating the line of a ditch the avoid-

secured and disposed of in such a manner that they can be emptied into or passed over it, accordingly as this additional supply may be needed or not. The ditch should be furnished with an abundance of waste gates, located at points where the escaping water will not be likely to wash away the ground and endanger the ditch, which, by means of these escapes, can be speedily emptied when a break occurring makes this necessary.

The route of the ditch having been selected with proper care, equal care should be observed in making the survey, in the prosecution of which the size and shape of the ditch and also the grades must be fixed. The character of material to be excavated must be examined; sites for flumes and tunnels determined, and where sustaining walls and trestles will be necessary—in short, all the information needed to enable the contractor to estimate the cost of building the ditch should be furnished by the engineer and surveyor. While a fall ten feet to the mile—three-eighths of an inch to the rod—has generally been deemed desirable as insuring a free flow of water, and at the same time protecting the sides of the ditch from excessive erosion, many of the ditches in the mining districts of California have a fall of 15 and some as much as 20 feet to the mile—narrow and deep ditches with steep grades, rather than broad and shallow ones, being here the rule; this rule, however, being departed from where deepening the ditch is likely to involve much additional rock work. Owing to the solid nature of the ground traversed by these ditches a swift current works but little harm. If at any point an extremely heavy grade becomes unavoidable, the water, unless it can be dropped at once, should be shot down through a flume, thereby obviating any hurtful washing away of the banks. While all ditches tend to enlarge themselves by the process of erosion, their banks gradually become solidified and thus, through diminished leakage and absorption, their carrying capacity is somewhat increased. In view of the loss of water caused by evaporation, absorption and seepage, it has been suggested that the ditch at its upper end be somewhat enlarged, tapering gradually to its normal size, thereby supplying water to make good the losses occasioned by these several causes of waste, that due to evaporation being very considerable during the California summer.

In length the ditches range from a few miles up to a hundred miles or more, exclusive of branches, the entire ditch system of some of our larger water companies covering a linear extent of nearly 300 miles. Generally the ditches in the counties central to the main gold belt are much longer than in the more northerly counties of the State because of the water supply of the mountains in the latter being so much nearer the mines. The cost of the main trunk of our larger ditches has ranged from \$100,000 to \$1,000,000, which sums have in many cases been increased from \$50,000 to \$500,000 for construction of branches. The capacity of these ditches varies from 600 or 800 to 7000 miners' inches—grade from 4 to 30 feet per mile, with an average of about 12 feet.

For further information in regard to length, size, grade and cost of ditches, water supply and consumption, reference is made to the ninth volume of this series of reports of the State Mineralogist, page 123, where a compendium of these and similar data will be found.

Treatment of Auriferous Pyrites.

A process has been patented by Mr. Florence of Peak Hill, N. S. W., for the treatment of auriferous pyrites by decomposition, says the *Mining Standard*. The principle is said to be so simple in operation that no skilled labor is required. Briefly, the inventor states it is Nature's own mode of decomposition hastened by chemical means. It is a well-known fact that heaps of auriferous tailings which have been left exposed to atmospheric influences for any length of time will, when tested by the dish, show prospects of free gold. Impressed with this object-lesson, and following up the clue thus given, the patentee proposes to subject tailings to the following treatment:

First, they must be concentrated, then dried and slowly calcined with ordinary agents until no free pyrites can be seen. The tailings are then placed in a solution under steam and boiling water, with cheap chemical agents, which finish the work of freeing the gold. Afterwards, simple amalgamation is all that is required. The process of calcining frees the acid—chiefly sulphuric—which works its own free will among the component parts of the pyrites. When the acid has done its work, the sulphides will be found to have formed soluble sulphates; and these, together with any alkalis that are not amenable to the heat, are neutralized and dissolved by the second part of the process. The product can now be placed in a Chilian mill and ground, and quicksilver added in the usual way. After the silver has been drawn off, the copper plate can be utilized to catch any little silver that otherwise must not have been obtained in the drawing off. The whole process, Mr.

BRACKET FLUME AND TRESTLE. MIOCENE COMPANY.

made by former workings, and from shafts sunk for the purpose; this prospecting work being carried always to as great depths as practicable, or as may seem necessary. For washing the samples of gravel so obtained, the pan sometimes, though more often the rocker, is employed. Where there exist facilities for using it, and there is much work of this kind to be done, the sluice should be availed of, and even the hydraulic pipe, if the ground has already been opened and equipped for active operations; the point sought to be enforced on the attention of the expert being that he perform this part of his work with thoroughness and accuracy. For a mistake committed in most other matters there may be found a partial remedy, but to go much wrong here is fatal and irreparable. And yet it is just here that the gravel inspector is apt to be deceived, if he do not deceive himself. There are often around those whose interest it is to mislead him. Then, very deceptive are these minute particles of gold, being the only ones he is likely to find in the top gravel where the most of these preliminary tests have to be conducted. Gathered in the pan or batea, these “colors” look big to the eye and much bigger under the glass, and yet it requires often a multitude of these almost microscopic atoms to weigh even a cent, whence arises the danger that our mine-viewer cheat himself if he does not suffer others to cheat him.

In this State, where all the conditions are first-class, gravel yielding a total of not over four cents per cubic yard can be worked by the hydraulic process with profit. As the conditions are less favorable, the grade requires to be higher; nor is it often safe to invest largely where the

ance of the above obstacles should be kept in view, earthwork, where the cost is not too great, being preferable to the building of flumes, especially where the latter require to be supported on elevated trestles, as these structures are comparatively short lived, needing also much repairing while they last. Beside being exposed to the wind and the likelihood of being blown down or destroyed by fire, they speedily decay, their average life not exceeding ten or twelve years. Better, as a general rule, carry your ditch by a considerable deflection around the head of a canyon than build a flume for transmitting the water across the depression encountered by a much shorter route.

But what is of still greater importance in this connection is securing an ample supply of water to continue, if possible, through the summer months, as then, the days being long, work can be prosecuted to better advantage than during other seasons of the year, while the water, warmed by the rays of the sun, promotes the action of the quicksilver, causing it to amalgamate with the gold much more readily than when the water is cold. In this style of mining, water failing, all work is intermitted—a good reason why the supply of water should be made perennial, if possible.

Again, the source of supply should be high enough to command the entire gravel deposit for which it is intended, as well as any other, if such there be, for the washing of which this water might at any time be made available. Being sufficiently high at the start, the ditch, in being carried forward, should be maintained at as great an elevation as practicable, to the end that ample head be insured for effective piping. Through faulty engineering, some of our pioneer ditches, when finished, demonstrated the soundness of the hydraulic theorem that water cannot be made to run up hill. It is always desirable that the head of the ditch be located below snow-line and have, as far as may be, a southern exposure. All water-courses on its line should be

*This article was prepared by the late Dr. De Groot for the Eleventh Report of the State Mineralogist, just issued; but its publication with that of much other valuable matter was prevented by the necessity of revision and omission, so that the volume might be reduced to reasonable limits. It covers familiar ground, but is, on the whole, a complete and careful review of the industry and hydraulic-mining methods. The article has been furnished this paper by State Mineralogist J. J. Crawford.

Florance says, takes from one to four hours, according to the nature of the stuff under treatment. The fumes can be condensed, and the health of the workmen protected. The cost in bulk, he states, will not exceed 20s. to 40s. per ton, and the lower price will often be maintained.

Important to Alkali Land Owners.

TO THE EDITOR:—The great importance of an abundant and reasonably cheap supply of gypsum as a fertilizer is recognized everywhere. Although not a universally efficacious fertilizer like the phosphates, its favorable effect on the legumes—peas, beans and clovers, (including alfalfa)—is enough, alone, to give it a prominent place in agriculture. Its special importance in California is due to the fact (first announced from the State Experiment Station) that it is an effectual antidote to the "black alkali" that afflicts some portions of the State, where it impregates the soil not so much in large continuous tracts as in spots varying from a fraction of an acre to several acres, where little or nothing can be grown, and which mar the continuity of fields, vineyards and orchards. Experience shows, moreover, that as a rule such spots extend their area as irrigation is practiced, invading bearing plantations of all kinds and causing loss and discouragement. Yet the fact that such lands when once reclaimed are profusely and lastingly productive, constitutes a strong incentive toward the utilization of the alkali lands, and renders the question of their reclamation for culture a very important one. The characteristic ingredient of "black alkali" being carbonate of soda, it follows that when gypsum is applied to land impregnated with it an exchange of chemical ingredients takes place, the soda being converted into "Glauber's salt" or sulphate of soda, while the gypsum becomes carbonate of lime, or chalk. Glauber's salt, with more or less of common salt, constitutes the "white alkali," which is rarely abundant enough in the soils to form a serious obstacle to their cultivation, being many times less injurious to vegetation than the carbonate of soda.

But gypsum acts not only as a neutralizer of the injurious effect of the carbonate of soda on the plants themselves; it is also of essential benefit in that it renders friable, and therefore tillable, the hardpan always formed in black alkali lands; moreover, it serves to retain in the soil the humus and phosphates which the soda has dissolved and which would be leached out of the land, to its great injury, if it were attempted to reclaim it by underdraining alone. These good effects have been verified in practice many times over, outside of the successful experiments made at the Experiment Station near Tulare. But until now gypsum—land plaster—has been rather too costly for general use on account of the heavy cost of transportation from a distance to the points where it is mainly needed, viz., in the upper San Joaquin valley; nor has quality of the material furnished been always satisfactory.

It is thus a matter of no little interest that a mine has been found and partially developed, which combines a location near the chief consumers of land plaster with an excellent quality of material easily mined and crushed for farmers' use. At the suggestion of Mr. John S. Dore of Fresno, the writer has lately visited the new mine and believes the results of the examination to be of sufficient general interest for immediate publication.

This mine is located in the ridges bordering the west side of the great valley, just north of Tome creek, and about five miles south of the Big Panoche. It was discovered in 1892 by Mr. J. H. Hall, of Selma, and is owned and worked by the Paoli Gypsum Company, of Selma and Mendota, Fresno county; the location being about 18 miles W. SW. from the latter station.

The main ridge, on which the gypsum appears at the highest level, extends about 2000 feet along the creek, to which it falls off steeply. Toward the north there extend from this ridge four spurs, from one-third of a mile to one mile long, on the crests of which the gypsum crops out abundantly, with a gentle dip toward the valley. The deposit on the crest of the main ridge, where most work has been done, shows a thickness of at least 30 feet, but its lower limit has not been exposed. At the foot of the east slope of the third spur (from the main summit), in a deep canyon and quite 150 feet vertically below the highest outcrop, there is a long exposure of a regular stratum about 18 feet thick so far as visible. Whether or not there exists a solid mass of the mineral from this outcrop to the summit cannot be seen; should such be the case the mass would be enormous, but in any case the deposit is a large one, sufficient to supply the needs of the San Joaquin valley for a long time to come.

The samples collected, which of course are essentially "croppings," show the material to be very nearly uniform from top to bottom; a yellowish-white chalky mass, easily crumbled and therefore readily put in shape for farmers' use. Eight samples were selected to represent the outcrops

on the crests of the several ridges, and also the one in the canyon mentioned above. The analyses of four of these gave the following results:

ANALYSES OF GYPSUM FROM PAOLI MINE.

	Gypsum.	Sand and Clay.	Moisture, Carb. Lime, Etc.
No. 1, from summit of main ridge	95.24	1.08	2.78
No. 5, from 2d spur, middle crest	94.74	1.52	3.74
No. 6, from 3d spur, in canyon	92.90	2.60	4.50
No. 7, from 4th spur, near road	82.20	8.21	3.75

These results render superfluous the analyses of the other four samples taken. It is probable that had the sample No. 7 been taken further from the surface, most of the sand it contained would not have been found, since the rest contain none like it. It is probable that the average of the deposit ranges above 90 per cent, since the only one of the samples taken in the mass of the deposit (No. 1, from the main workings thus far done) is the highest of all, and, counting out the two per cent or thereabouts of atmospheric moisture, is probably equal in purity to any thus far found in quantity west of the Sierra Nevada. Selected portions of the deposit will undoubtedly be available for burning into plaster of Paris for builders' use.

It is thus obvious that whenever this mine shall be worked on a proper technical basis, the other mines now supplying plaster will have to look to their laurels in competition with it.

Ore Chlorination in Arizona.

Abridged from Letter of Robert DeLarge to Prescott Courier.

The concentrated sulphurets or arsenurets are subjected to a treatment of chlorine gas after a thorough oxidizing or chloridizing roasting. The chlorination works should be located with reference to the prevailing winds, with proper elevation of ground and a good supply of pure water. The sulphuric acid and chloride vapors are very destructive to all kinds of machinery they come in contact with. For roasting I prefer a double or treble Terrace drop furnace. The furnace is slower and requires more labor to handle the ore while roasting, consequently is more expensive. The ore, while being roasted, should be kept at dark red heat, and when started with working scrapers, show a few sparks; it is then ready to salt; then the chloridizing roasting proper begins. This is generally after a preliminary roasting of from four to five hours. Every ore is benefited by the use of salt, as the consumption of chlorine in the subsequent pregation is reduced thereby, aside from the advantage of a purer precipitate of gold, by the protosulphate of iron. Quantity of salt to be used ranges from three to ninety pounds per ton; large quantities are used when there is a good deal of lead.

When the ore is not thoroughly cooled before the treatment by the chlorine, a greater consumption of gas is the consequence, aside from a smaller amount of gold extracted. We shall now proceed to the dissolving vats, the insides of which are coated with a plastic coating of pitch and tar previous to using the first time, and thoroughly soaked in water to prevent impregnation of gold and loss. Each tank has a perforated false bottom so as to let the gas enter at the bottom and ascend to the top. When the gas is seen raising to the top of the vat the peep-hole is closed and a lively current of gas kept up for a few hours, the usual time ranging from five to ten hours to impregnate. The gas is generated in a leak gasometer, the cover of which is made gas-tight by means of a water joint; the acid is introduced through a bent lead pipe; the charge for the gasometer consists of a coarse rock salt, binoxide of manganese and oil of vitriol, to which is added water. When the lid of the vat is opened, the strong odor of gas is a sign of good work. Warm water is turned on carefully and the clear yellow solution is run through a canvas bag into a barrel, is conveyed from the barrel by a hose attached or inserted at the side to the precipitating tank. The solution when run into the tank is so delivered as to give the liquid a rotary motion, facilitating the coagulation of the gold particles and their final settling. The articles or materials used for precipitating are sulphate of iron and oxalic acid. The gold now at the bottom of the tank is a brown, earthy looking mass. The water is drawn off by means of plugs on sides of vat, the gold gathered up, squeezed through a cloth, dried and melted. If any precipitating takes place within the dissolving cast it is evident that so much of the gold is lost. The precipitating agents to be avoided are sulphur, antimony, arsenic and iron, though the peroxide of these metals is not injurious; therefore, complete roasting is essential to doing thorough chlorination.

There are many details I have omitted, such as the different kinds of ores, how to dispense with hydrochloric

acid, etc. This, I think, will give you a rough outline as to the reduction of ore by the chlorination process, and ought not to cost more than \$10 per ton.

The First Hydraulic Mine.

TO THE EDITOR:—I know there are other claimants to the honor of first applying the hydraulic in mining; I think, however, the claim of Mr. E. E. Matteson to that honor can be easily substantiated. He is now a poverty-stricken, broken-down old man, living in Nevada county. His story can be substantiated by old settlers who know the facts, some of whom now reside in San Francisco. I believe Mr. A. E. Head and Lee D. Cragg have personal knowledge of the facts narrated by Mr. Matteson; probably Judge Niles Searls, also; they were all at Nevada City at the time. The following is Mr. Matteson's statement of the event:

"I was mining in the spring of '53 at American Hill, about a mile west of Nevada City. We had a ground sluice and flume, and employed eight men. The bank was pretty high, and the danger from its caving considerable. One cave nearly caught me, wrenching a pick from my hand. I had spoken to my partners about using the water against the bank under pressure. The danger impelled me to put my theory into practice. I constructed a hose, four inches in diameter and 40 feet long, out of rawhide, with the hair on the outside. Of course, as this became wet it stretched, and when it dried it shrunk. The nozzle was $\frac{3}{4}$ inch, made of sheet brass enclosed in a wooden jacket. We had 30 feet fall, and at first used a nail keg set on a stump on the edge of the bank for a bulkhead; afterwards we put up a pork barrel in its stead. Before that we were using 12 inches of water, which carried away all of the dirt our men could dig. When we put up the hydraulic apparatus we hought 17 inches of water and with it knocked down more dirt than our flume and the water would carry away, having occasionally to stop until the flume cleared. We used the apparatus three months, and created much interest. After it became known that we were using it we averaged over 50 visitors per day. We hought the water from Jas. Whartenby, and the hooks of the company at Nevada City now show the amount we purchased, and that we paid 75 cents per inch for it. Our water bill was \$153 per week. For quite a while the claim yielded four partners \$50 profit per day each."

Mr. Matteson is a native of Rhode Island, aged 71 years, and besides making the first application of the hydraulic in mining, has made other valuable inventions.

Grass Valley, Cal., Dec. 28, 1893. CHAS. W. KITTS.

Placer Mining in Alaska.

Abstract from Description in Portland Oregonian.

The mining season only lasts three months in the year. The season opens about the middle of May and closes about the middle of September, and during those months the miners work like bees. The deposits in the stream are very rich in gold. The best diggings yet found in the district are on the Miller and Davis creeks, where the placers yield from five cents to \$1 a pan. I think that this year has been a more successful year for the miners than any previous one. It was estimated that \$750,000 in gold was taken out of this district last year, and I am quite confident that there was considerable more taken out this year. Where the condition of the country will permit, trails have been made, but most of the route is up and down mountains, across divides, over glaciers and by fording rivers. The most of the travel is done on foot, although parts of the distance can be done on sledges drawn by the Esquimaux dogs. Snowshoes are also used some. This system of travel is kept up continuously for over a month, when you have the satisfaction of arriving at Forty-Mile creek, and right before your eyes is a little village, consisting of log houses and about 300 miners. The scene would probably remind you of pictures you had seen of New York during the time of the early Dutch settlers. Here times are the same all the year round—no bank failures or no absconding treasurers to cause panics and dull times.

In the winter season the principal thing we do is to keep warm, and about all we do outside of that is to read, eat and sleep. Wood for fuel is scarce and we have to haul it over 12 miles on sledges drawn by dogs. We use the genuine specimens of Esquimaux dogs on our sledges. The miners have been experimenting on raising Esquimaux dogs, and as a result their dogs are larger and stronger than those of the Esquimaux and Indian. Two horses were brought into the district this year and they are doing well. They are fed on the native grasses and are looking fat and sleek. Our food is all shipped to us by the trading companies on the Yukon river. The only vegetable that we can raise for food is the rutabaga turnip. It is raised quite extensively by the miners and is a fair looking specimen. To give you an idea of what it costs to live in the

January 6, 1894.

mining districts of Alaska, I will quote a few prices of some of the necessities of life: Flour is worth \$15 per 100 pounds; bacon, 35 cents per pound; beans, 17 cents per pound; tin plates and cups, 50 cents apiece. A wooden shirt is worth \$7 and a pair of overalls \$2. The miners who go into that country earn their money, and the privations that a man goes through are oftentimes worth double the money which he takes away with him.

Influence of Country Rock.

Abstract of article in *Colliery Engineer* by Prof. Arthur A. Lakes of Colorado.

In most mining regions a relation has been observed between varieties of "country rock" and ore deposits. Veins in passing from one country rock to another are liable to change in the size or variety of the ore, widening in connection with some rocks, and pinching or growing narrower in connection with others.

Certain rocks are notorious ore-bearers, while others are notoriously barren over large regions, or in special localities.

The presence of certain rocks adjacent to other different rocks has an enriching tendency on the ore bodies.

As regards rocks that are good ore-carriers or receptacles of particular classes of ore in Colorado, we may say that quartzites and silicious rocks generally carry more pyrites, and are gold bearing.

That veins in granitic rocks carry a greater variety of minerals than others, and may be both gold and silver bearing.

That certain limestones carry much argentiferous galena.

That sandstones and other unaltered rocks carry little ore of any kind.

The influence of country rock on veins may be from several different causes, for instance:

Certain rocks are by their structure better adapted than others for forming regular fissures. Thus, massive limestone is better fissured than slate or shale, leaving wider open spaces for the ore to collect in.

Other rocks may be more porous and admit mineral solutions through their pores. Of such a kind are some of our porphyries.

Others, like limestone, are easily acted upon by solutions dissolving out the rock and replacing it with mineral by substitution.

Some are better conductors of heat, and therefore would assist chemical action and mineral solution.

And lastly, if modern theories of "lateral secretion" be true, viz., that most ore comes from the adjacent country rock and is precipitated, substituted or collected in the vein fissure, and further, that the metals themselves are derived from certain metallic elements in the ordinary constituent minerals of the country rock, such as mica, hornblende or augite, it is clear that a rock composed largely of such minerals would be liable to influence the vein as an ore generator. Granite and porphyries are largely composed of these minerals.

The frequent presence of eruptive porphyry rocks near veins and ore deposits in Colorado shows that they have an important influence on those deposits, which may be of various kinds:

First, that in their component minerals and mass they actually contain the elements of the precious metals subsequently deposited in another form in the fissure vein or in the soluble limestone in contact with it.

Second, by the heat which they retain for a long time after they have congealed and hardened, they would assist in the reactions of any chemical or mineral solutions that might be on hand. Lava, at the time of its eruption, is always highly charged with steam and other gases. By reason, also, of the chemical composition of porphyry, waters passing through it would be alkaline and assist in dissolving silica and other gangue or veinstone matter, and when the porphyry has thoroughly cooled it is exceedingly porous, and being much jointed and cross-fractured, becomes like a great sponge for the absorption of all surface waters. This may be noticed at Aspen, where all the mines that are at present penetrating through the "porphyry cap" are much troubled with water, far more so than in the underlying limestone. Surface waters, then, becoming alkaline by passing through this rock, and also more or less charged with carbonic acid, chlorine and other solvents, would be ready to dissolve both gangue and vein ingredients out of the porphyry and redeposit them in the vein fissure, or, by metasomatic substitution, in the limestone usually beneath it.

Water circulating in fissures changes or dissolves the ingredients of the surrounding rock. The rocks enclosing lodes are always so altered, and this decomposition and alteration is not always merely local or confined to the close proximity of the ore body, but we often find a whole mining district pervaded by this feature. So much is this the case that it is often difficult to get a fresh, unaltered

specimen of porphyry or some other country rock within the district.

"In lodes a mutual exchange takes place through the reaction of the ingredients of the rock and the materials of the vein. Thus, when water containing carbonates comes in contact with the rocks or minerals containing alkalies, a chemical reaction takes place. When these last are combined with silicic acid, these silicates are decomposed by the carbonic acid and the bicarbonates. This explains both the crystallizing out of the carbonates and the so frequent decomposition of rocks containing lodes, especially those which, like our veins of granite, are feldspathic."

The same principle applies to other ores and minerals in lodes. Thus the precious metals in the mines of Leadville in their original condition have been proved by depth to have been in a sulphide state such as iron pyrites (sulphide of iron), or galena (sulphide of lead), etc. Surface waters charged with carbonic and other acids, passing through the overlying porous alkaline porphyry and entering the underlying limestones, have, as we have previously observed, changed the sulphides into sulphates, oxides and carbonates. The presence of a dyke near to or cutting a vein has been found often to enrich the latter at the point of contact.

There is often a prejudice among miners in favor of certain rocks and formations, and against others. Miners who have worked perhaps in the great Comstock mine of Nevada, or the Leadville mines of Colorado, or the fissure veins in granite of the Old World, are apt to look out for and favor certain rocks and formations they find like those they have been accustomed to. Thus, as Mr. Williams says, "The peculiar 'porphyry' of the Comstock was hunted up in other districts, but did not prove metalliferous. Solid granite was looked upon by others as unfavorable, generally, because locally some granite above the gold belt of California had proved barren. Yet some of our best veins are in granite."

"Limestone was at one time a very unpopular rock and supposed only locally to produce lead, till the discoveries of Leadville and Eureka, Nevada, overturned the scale in its favor."

In the Leadville "excitement" not only was the particular carboniferous limestone of Leadville hunted for and prospected, but every other limestone in the South Park region, no matter what its geological age or position, was extensively prospected without results, miners not recognizing the fact that it was not limestone generally that produces rich ores, but a particular limestone of a particular geological period (the lower Carboniferous), not over 200 feet thick, that happened locally to be rich near Leadville, and the reason of its being locally rich at that point was owing to the concentration of eruptive energy at that point and the intrusion of an unusual amount of porphyries, which in point of fact are far more responsible for the ore than the limestone, which happens to be merely the receptacle.

It is not a particular rock or formation but a combination of favorable circumstances that alone can make a rich mining district.

As experience advances geologists and miners have proved that ore deposits have a much wider range than was once supposed. Formerly only the Archæan granite series was supposed capable of bearing ore deposits, because in the Old World, tin, copper and lead came principally from fissure veins in those rocks. Then deposits were found in the Paleozoic series and supposed to ascend no higher. But in the present day they are traceable even to the Tertiary.

It is not the rock nor the age, but a combination of circumstances, principally heat and metamorphism, that may make any rock of any period an ore-bearing one. And in prosecuting in new regions it is these combinations rather than any particular rock that should be looked for.

The Kimberly Diamond Mines.

It is not generally known that the Kimberly diamond fields are no fields at all, says an exchange. This mine is the actual crater of an extinct volcano; in fact, there are two of them. The miners have dug out the crater already to a thousand feet level, and looking down from the top it seems like an enormous well, the superficial area of it being six acres. They will never have to stop digging for diamonds until they get to that point beneath the earth's surface where the elements are in a liquid state. It requires a peculiar treatment to get the stones.

The blue stone, of something like the composition of our red sandstone, is dug out by the miners, is treated to exposure and water for some six months before it crumbles, and then is washed in a great pan. The average yield of diamonds is about three and a half carats to the ton, and some idea of the enormity of the deposits can be obtained when it is said that there are at times upon the floors of the

mines where these rocky deposits are placed something like \$23,000,000 worth of diamonds. The average of deposits is so thoroughly maintained that it is now easy to estimate what the value of each load brought from the bottom of the crater is.

These diamonds are sold to the agents of European diamond-cutters, although the yellow and rose-colored stones go for the most part to India, where they are very highly prized. A pool of English diamond-dealers recently bought a million and a half dollars worth of them. And the usual purchase made by any one party or syndicate is about \$250,000 worth.

The largest diamond mined, at least in recent years, which was taken out a few months ago, weighs 972 carats, is $3\frac{1}{2}$ inches long and $2\frac{1}{2}$ wide.

The parties who got this diamond paid only about \$8 a carat for it, since it came out with a lot which they had contracted to take within a certain time. Had it been discovered six hours later the parties would not have received it, for the contract would have expired.

The Laws of Optical Projection.

A recent controversy among electricians as to the photometric classification of search lamps suggests a few simple reflections on the laws which govern the intensity of projected light, says the *Optician*. Ordinarily, if the wave front be completely spherical, the law of inverse squares is exactly obeyed; but when a lens or a mirror is introduced, this is no longer the case, and the light now obeys some special "law of the projector."

The most curious law is that of the parallel beam. Some one proposed to utilize the constant intensity of such a beam in flashing signals to the neighboring planets, or to mount together a pair of large telescopes, with parabolic mirrors, place a very powerful light at the focus of the one, and through the other examine or photograph spots on the unlighted surface of the moon, etc. In photometry, the peculiarity of the parallel beam is that the candle-power, in the ordinary way of reckoning, increases, as the angle illuminated diminishes, with the distance from the source of light. Candle-power is ordinarily measured and expressed independently of the size of the photometric screen, and upon the assumption that the light, uniformly distributed, illuminates an area increasing with the square of the distance from the source. With a parallel beam, of course such a measurement of candle-power is without meaning. It eventually becomes infinite, if conducted at a sufficient distance from the radiant. With a converging beam, on the other hand, this nominal candle-power first increases, but not indefinitely, and afterwards diminishes with the distance.

No method of producing a very powerful parallel beam has yet been devised. Perhaps from that ignited molecule which happens to lie exactly at the focus of the parabolic mirror in a search lamp, a truly parallel beam of light may be emitted; but the surface generally of the radiant must lie without the optic axis. Hence in the construction of a projector one can only aim at obtaining an approximation to the required distribution of the light in a field at some given distance. The proper basis for an estimate of the candle-power is the illumination of the whole field; and on this basis, disregarding atmospheric absorption, the total amount of the light should be everywhere the same. To illustrate this way of designating the luminosity of a surface, we may mention an estimate of Lord Kelvin's which places the light of the full moon at some forty thousand million-million candle-power. This is the number of candles (roughly corresponding to the separate radiant particles of an ordinary luminous surface) that would have to be packed in close order, on the dark hemisphere of the moon, in order that it should emit the same light as at the full. In travellog to us this light is weakened by the inverse square rule; and so also would the exploring spot of terrestrial light mentioned in the last paragraph, even if it could be projected in the way described. Clearly, this simple dependency of the intensity of a given quantity of light upon the extent of the surface it illuminates—which resembles the dependency of the thickness of a uniform plate of known weight upon its area—is better accorded with by almost any of the proposed standards of light than by the "standard candle," of which the luminous area is quite indefinite. It is far better to make use of a square centimetre or a square millimetre of surface area of some incandescent solid. It will have been noted as a consequence of what precedes that there may be a great difference between the nominal candle-power of the beam projected by an optical lantern and that of the same light after dispersion by the lantern screen. In the first case the field of illumination is a small one; in the second, a complete hemisphere. Again, in the converse case, the "candle-power" of a lamp used in the ordinary way is, of course, enormously less than it is possible to be made by an optical collecting system.

Scientific Progress.

Gasification of Coals and Liquid Hydrocarbons.

In a paper on the above subject, Dr. P. Dvorkovitch, of London, stated that the present method of gasifying coal must be abandoned and the temperature lowered. He expected that such a radical opinion would meet with great opposition from gas engineers and chemists, but the value of the industry was too immense to let that prevail. In explaining what by experiment he had found possible, he would assume coal to be fixed carbon saturated with hydrocarbons, mostly belonging to the paraffine series. As far as he knew, Mr. Taylor was the first to obtain a patent for the manufacture of oil gas, in 1824. Shale oil was used, and the apparatus employed was so simple that Mr. Taylor was able to form a large company to work it, through which there were lost \$340,000. Taylor's apparatus had been varied by many inventors, but all had the same view—the gasifying of the whole of the oil—and therefore all had failed. The high price of liquid hydrocarbons and the absence of proper chemical knowledge of the method of gasification had hitherto resulted in failure. The attempt had been made to gasify the whole of the oil treated, without leaving any residuum, and, unfortunately, most of the inventors had succeeded in this attempt. The gasification of oil has been based upon the method of gasifying coal—namely, to destroy the unsaturated hydrocarbons; and this had been the main cause of wastefulness. In Russia, although the gasification of oil was carried on mainly with a view to obtaining by-products, yet under certain conditions the same quantity and quality of gas were obtained as in England. Of course, in western Europe and America, where gas was largely used, it was natural that the production of gas should be made the main object; but in Russia, where gas was little used, the chemists had to devote their energies to the production of by-products.

In the experiments he wished to detail he had employed three distillates—solar distillate of 0.8625 specific gravity, special solar distillate of 0.8852, and special distillate of 0.8891. He gasified them in an apparatus consisting of two iron pipes laid one above the other, and connected at one end. Distilling solar oil at 1600° F., he obtained 120 cubic feet of 22-candle gas per gallon, or 576 candles per gallon, and 32 per cent of bye-products. At 1300° F. the yield of gas was lower, but the quality was much higher—the candles per gallon were 665, and the by-products were also much larger in quantity. It seemed to him that from the first invention of gasification down to the present day an enormous loss had been going on, and it was really wonderful that the subject had not attracted more attention.

Discovery of the Telescope.

As in many other cases of discovery, that of the telescope appears to have been the result of a playful accident, says the *Optician*. Several stories are told about it, but they are all similar. The one most generally accepted tells how, about the year 1590, just 303 years ago, the children of Zachariah Jansen, a spectacle-maker, residing at Middleburgh, in Holland, were playing one day in their father's workshop, and observed that when they held between their fingers two spectacle glasses, one some distance from the other, and looked through them at the weather-cock on the church, it seemed inverted, but very much nearer to them and greatly increased in size. Their father, when his attention was called, saw that one of the glasses was convex and the other concave. He made experiments, and ended by fixing such glasses in wooden tubes a few inches long and selling them for curiosities. An-

other account tells us how one Lippersheim discovered the telescope in a similar manner. Descartes, however, a contemporary, gives the credit to James Metius, a glass-cutter in Holland, whose brother, a professor of mathematics and a maker of burning glasses and mirrors, hit upon the discovery in the same way that Jansen's children are said to have done.

Diamonds in a Meteorite.

When the first announcement was made a little over two years ago that small diamonds had been found in a mass of meteoric iron picked up in the Canyon Diablo, Arizona, it was received with some skepticism. The tests made, early in 1891, with these particles, employed acids against which the alleged diamonds were proof, and abrasion with corundum. This latter substance, one form of which is emery and another the sapphire, was then the hardest known to science, with the exception of the diamond itself; and corundum was as easily scratched by the minute points hidden away in the Canyon Diablo meteorite as gypsum is with a knife.

A number of other experiments were tried by various experts; and finally Mr. George F. Kunz, associated with Tiffany & Co., of New York City, suggested that if enough of the wonderful grains could be procured for that purpose, it might be well to try to polish a diamond therewith. In the latest number of the *American Journal of Science* Mr. Kunz (in co-operation with Dr. Oliver W. Huntington) describes this attempt, which was made at Chicago during the closing days of the Fair. A rough diamond, lent by Messrs. Tiffany & Co., was tried first upon a clean, new wheel, making 2500 revolutions a minute; and at the end of five minutes it had not been scratched. Upon the surface of the wheel Mr. Kunz then put a mixture of the particles whose character he desired to ascertain, with oil; and the instant the diamond was freshly applied a hissing and grinding sound was heard. In three minutes a face had been cut and polished on the diamond. A smaller crystal was similarly tried afterward with the same result. A new substance called carborundum having been discovered (or invented) in the last year, this was now tried upon a stone known to be a diamond. Not only did it fail to affect the jewel, but it was itself scratched thereby. Thus it was proven that the mysterious particles were fully as hard as the diamond, and the other evidence that they were, indeed, black diamonds themselves, received corroboration.

This is the first instance of the kind on record. A meteoric stone picked up in Russia in 1887 was suspected of containing diamonds, but the suspicion was never verified. The particular grains found in the mass from Canyon Diablo were too small to possess a commercial value, and their quality, too, was not what a jeweler would demand. Nor is it likely that the market will ever be supplied from similar sources. What renders the Canyon Diablo discovery of the most interest, therefore, is the fact that Nature, outside the limits of this planet, has been working as the French chemist, Molssan, did about a year ago; crystallizing into diamonds carbon which had first been absorbed by superheated iron. It may not be many years before jewels far superior to either of these products are manufactured by man.

Light Intensity of Tints.

Mr. Joseph W. Lovibond has described, in a work entitled "The Measurement of Light in Color Sensations," the arrangement and applications of his tintometer—an exceedingly useful instrument for measuring and defining the exact tones and densities of colors. The peculiarities of Mr. Lovibond's apparatus and system include the use of graduated colored glasses as standards of comparison, of appliances for excluding side-

light, and for giving a direct view without the use of lenses, prisms and reflectors. In addition, the author has a whole scheme of color notation and nomenclature, whereby the faintest tints noticeable to normal vision may be named and classified. He poses as the three primary colors—orange, green and violet; and he limits the number of separate color sensations to 12, six of which are simple and six compound. The practical applications of the tintometer are already numerous. It is extensively used in the examination of water, in the analysis of steel, and in paper making, flour milling, etc. Indeed, it is obviously indicated for use in any industrial process which involves the employment of the eye in judging colors. This has hitherto been dependent upon the interpretation, which may easily vary with different interpreters, of such terms as dull red, white hot, etc., and it must be of advantage to be able to assign a numerical equivalent to such vague expressions.

Mechanical Progress.

Boiler Tube Cutter.

The Le Vasseur boiler tube cutter for cutting out old tubes or flues for removal or otherwise, and for turning off new flues or cutting pipe, consists of a mandrel conforming loosely to the size of the tube to be cut, in which are knives or cutters radiating from and attached at their base to a mandrel (within the before-mentioned mandrel) of varying diameter and provided with a screw by means of which the knives may be fed out as the cut in the tube progresses.

In operation the tool is placed in the tube with the knives at the point to be cut. The

tool is then revolved by means of a ratchet and handle and the nut is held stationary, which gradually draws the inner mandrel toward the handle, thus bringing the larger diameter under the heels of the knives and throwing them out against the inner wall of the tube, the operation continuing in this manner until the cut is completed. In removing the tool from the tube the nut is run back to its original position, allowing the inner mandrel to be pushed away from the handle, retiring the knives into their sockets.

It works rapidly, makes a clean cut without splits or breaks. It is manufactured by the Gouverneur Machine Company, Gouverneur, N. Y.

Amalgam Cement for Porcelain.

A very stable and lasting cement for articles of porcelain that do not have to be submitted to a very great degree of heat is made, according to the *Farben Zeitung*, as follows: First prepare a fine powder of metallic copper, by shaking a solution of copper sulphate with granulated tin. Wash the powder well after precipitation. The proportion of this powder will vary according to the desired hardness of the cement (which is, in fact, an amalgam), and may run from 20 to 36 parts, the rule being the more copper, the harder the cement. Place the desired quantity in a porcelain vessel and add to it sufficient sulphuric acid of 1.85 s. g. to make a pasty mass. Add at once 70 parts of metallic mercury and stir constantly until a homogeneous amalgam is obtained. Wash with plenty of warm water until all the sulphuric acid is removed. To use this amalgam, it must be heated until it becomes like wax. The edges of the article to be united should also be heated to about

375° C. (about 706° F.) When applied to the heated amalgam, a portion of the latter will attach itself to the edges, which may then be joined. As soon as it is cool, the article is ready for use. It will then stand heat up to 500° F. without any danger.

Making Large Steam Pipes.

At the New York meeting of the American Society of Mechanical Engineers, Mr. C. H. Manning read a paper in which he described a method of manufacturing large steam pipes which he employed 11 years ago for several thousand feet of 20-inch pipe, with very satisfactory results. The pipe was made of mild steel $\frac{1}{4}$ inch thick, double riveted, and with die-forged flanges $\frac{3}{4}$ and $\frac{1}{2}$ inch thick. The pipe was riveted with an Allen pneumatic riveter having 70-inch reach of arms which limited the length of sections. The longitudinal seams were placed quartering 45° from top of pipe, with the laps pointing up so as to be readily accessible for calking. The quarter turns were made of two 5-16-inch sheets curved on a cast-iron former, and having a row of rivets along the back and another along the throat. The tees were made of three sheets, shaped over similar formers, and the rivets were all on the sides. A serious difficulty had been previously experienced in keeping the round-

about joints tight. Leaks had been caused by condensed water retained by these seams, which caused unequal expansion, as the portions covered by them heated much slower than the unprotected or dry surfaces. This was remedied by making the section conical and bringing all the laps in one direction, and then laying the pipe on a down grade with the smaller ends the lowest so that the water ran out. The last course of the pipe was not coned, to avoid having two sizes of flanges. Mr. Manning has never known a riveted pipe to give out under water hammer, and a hammer that would completely wreck a cast-iron pipe or split a welded pipe would only strain the longitudinal joints of a riveted pipe.

Soldering Aluminum.

By means of the alloys mentioned below, aluminum or other metals, such as iron, tinplate, zinc, copper, brass, nickel, it is said, can be rapidly and easily soldered, either with the brazing iron or blow pipe. Aluminum can also be soldered to any of the above metals; the material is cheaper than any hitherto employed, gives a solid joint and does not injure the metal by oxidation or otherwise: (1) Unalloyed pure tin, melting point 250°; (2) tin 1000, lead 50, melting point 280° to 300°; (3) tin 1000, zinc 50, melting point 280° to 320°; (4) tin 1000, copper 10 to 15, melting point 350° to 450°; (5) tin 1000, nickel 10 to 15, melting point 350° to 450°; (6) tin 900, copper 100, bismuth 2 to 3, melting point 350° to 460°. The first three do not color aluminum and can be used for ornamental and artistic objects. Four and five are yellowish in color, but have the advantage of higher melting point and greater strength and hardness, and suggest the pos-

sibility of using aluminum for various articles and purposes for which hammered, coated, or enameled iron, tinplate, copper, zinc, lead, etc., are now used. The *Journal* of the Society of Chemical Industry says the last alloy can be made to assume any tint of yellow by varying the proportion of copper, and is therefore suitable for soldering aluminum bronzes; the proportion of bismuth is adjusted so as to keep the melting point suitable for the use of the brazing iron.

To Wash Carbon from Smoke.

The directors of the Birmingham, Eng., mint have adopted a practical method of remedying a long-endured nuisance. The thick black volumes of smoke proceeding from the high chimney-stack of the local mint have long been a series of annoyance to the district, and the shop-keepers especially have suffered to no inconsiderable extent from the same source of trouble. The Mint Company has suffered perhaps as largely as any one in the vicinity, and has had on many occasions to answer the complaints of the health inspectors and to pay heavy penalties incident to the proceedings that have from time to time been taken.

The Birmingham *Gazette* says that recently a gentleman who owns a large joinery establishment at Newbury, Berkshire, expressed his willingness to wash the smoke by an original process of his own. The invention which he has introduced at the mint has met with the entire approval of the directors of the company, and has also given satisfaction to the health authorities of the city.

First the smoke is drawn from the stack by a powerful fan, and it is then forced through a revolving cylinder into a tank filled with water. Perforated heaters are attached to the back of the cylinder, and these drop into the water and scrub or wash the smoke, which is put back into the chimney in the form of a perfectly pure vapor. The solid carbon which is washed from the smoke is brought out at the bottom of the tank all bubbling and boiling over, to all appearances a black, foaming froth.

The arrangement of the apparatus allows an inspection of the washing process, and of the vapor, which, after the cleansing has been performed in the tanks below, is perfectly white and odorless, and is thrown through the chimney into the air as steam. It is an interesting fact that the black extract is admirably adapted for use in the composition of paint and printing ink, while the ammoniated water remaining after the process of washing possesses the properties of a powerful disinfectant.

Fuel of Steamers.

The American liners New York and Paris burn about 330 tons of coal per day, or about 30,800 pounds per hour, and maintain about 18,000 indicated horse power, which is equivalent to a coal consumption of 1.71 pounds per hour per horse power. The average for all the fast ships with triple expansion engines, like the New York, Paris, Majestic, Teutonic and Furst Bismarck, is probably only about 1.75 pounds per hour per horse power. In the case of the Umbria and Etruria and similar ships, which have only compound engines, the rate is higher. For example, the Etruria burns as much coal as the New York and more than the Teutonic, and develops far less power than either of them, which illustrates the great advance made in marine engineering by the introduction of the triple expansion system.

MAKE YOURSELF A MINE FOREMAN,

Superintendent, Mining Engineer (Coal or Metal), or Successful Prospector by devoting your idle hours to HOME STUDY, BY THE METHOD OF THE CORRESPONDENCE SCHOOL OF MINES, SCRANTON, PA. To begin, Students need only know how to read and write. MODERATE CHARGES. SEND FOR FREE CIRCULAR.

McPHEE Building, DENVER, COLORADO

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.
Price, \$3.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.
The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulas as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Useful Information.

Varnishing.

Varnishing is a subject that has been written on time and again, and may seem to old and experienced finishers to be almost worn out, says *Varnish*. But they must remember that because they can go ahead and produce a first-class job, that there is a younger class of painters growing up who lack the experience and knowledge possessed by the veterans.

I sometimes wonder why a certain article was published, as I knew all about that subject, but then it occurs to me that perhaps some one else didn't know all about it, and it would benefit them. There are some men who haven't the opportunities they should have; there are some who do not avail themselves of their opportunities; there are some who do not combine judgment with their experience; some who never read a trade paper; some who never get anywhere beyond the shop in which they work. All these men have much to learn, if they only will.

In varnishing a job, I claim that nearly as much responsibility lies with the rubber as with the finisher, for if the job is poorly rubbed and cleaned, the job will not be up to the standard when done, no matter how good the finisher is. But the finisher must shoulder all the blame.

I once worked in a shop where they always used the best rubbing varnish to finish with, so that it could be rubbed down and have another coat of the same at some future time. That painter had neither judgment nor confidence in himself or he would not have been afraid to use wearing body varnish instead of a rubbing when he went to finish. He was always nervous and fidgety over the results.

We all think our ways are the best, because we have become familiar with them and we obtain good results. But I don't see that the process makes much difference so long as we produce the desired surface and finish.

I think it is necessary to get acquainted with the varnish we use and learn its peculiarities. Afterward we can make the varnish do about what we want it to do, with judgment mixed in.

As a rule, it is the man who is always shifting from one varnish to another that is always in trouble over his work. Find a good standard varnish that you can handle and then stick to it, and the longer you use it the more familiar you will be with its workings and the better will be the results.

About applying the varnish: Don't be afraid of it, and don't get nervous over it, but be bold and let the varnish know you are not afraid of it. Then you can handle it as you like, and that is all there is to it. Take a panel and apply an even coat all over it, putting on all you think will lay there and flow out full, wipe out your corners and top and bottom edges lightly and then leave it. If the temperature is right, and wind and weather favorable, you will come out all right.

Safety Elevator Device.

The hydraulic hoists for the accommodation of traffic in the tunnel under the Clyde at Finnieston are so far completed as to undergo tests, says the *Colliery Guardian*. One of the principal devices of the hoists consists in dogs automatically projecting into the guides and stopping the movement of the car when any of the ropes break or even show signs of slackening. The tests were directed to ascertain the efficiency of the gear by which the dogs or great clips are to be worked at Glasgow.

A heavy timber frame was used to serve the purpose of the great shafts sunk in the quay walls at Glasgow. This frame was 20 feet high, and in it was suspended a temporary cage arranged to be dropped sud-

denly with greater shock than would be the case even with ropes breaking. This was done by the pulling of a trigger. This cage, which with its attachments weighed 1630 pounds, was loaded with 30,221 pounds, so that the weight of all was over 14 tons. Two cords were attached to the cage to represent the governor rope of the completed cage, and these were arranged to operate the dogs when the rope actually suspending the car gave way. The greater the distance the car fell the greater the stress on the dogs or clips. The actual resistance of the pair of safeties was 52,830 pounds, or 26,415 pounds each.

When tested, the cage dropped a total distance of two feet ten inches, at which point it came to rest. With the gear on the north side of the cage in operation the cage fell 13½ inches, and was stopped in a further distance of 20¾ inches, while with the gear on the south side in operation the cage fell 13½ inches, and was stopped in a further distance of 20½ inches. The average was therefore a fall of 13½ inches and stoppage in 20½ inches, so that the cage was only able to drop two feet ten inches after the ropes broke, when it was brought to a complete stop. This is very satisfactory when the great weight is considered. Moreover, it was found by calculation that when the safety gear went into action the car was traveling at the rate of 8.4 feet per second. The cage was brought to a stop without any shock, the foreman in charge of the tests being upon the temporary staging on which the weight and cage dropped.

Coke Sweating.

Wm. N. Page, of Ansted, W. Va., makes an interesting statement on the phenomenon of coke sweating. While he does not attempt an explanation, he certainly cites observations sufficient to leave no doubt as to the facts he presents. He says: "A series of observations which I have made through a period of ten years, and with different cokes, has shown that during the hot summer months dry coke, containing not more than one per cent of moisture, drawn fresh from the ovens, and loaded directly into tight box cars, without any contact with water on the yard, and in the absence of any rain, will become saturated with water when the car doors are tightly closed, but when slatted and left open no such phenomenon appears. In a car so loaded with coke drawn from a bee-hive oven at red heat, and with closed doors, at the end of a week water would be dripping through the bottom of the car, and the coke would average from five to ten per cent of water, while in a similar car, loaded at the same time, with doors left open, all other conditions being the same, the coke contained less than one per cent of water. If these conditions are based upon facts, as is indicated by observation, what is the chemical explanation? We know that dry carbon, notably fresh charcoal, possesses the peculiar quality of condensing, or quietly combining oxygen and hydrogen, but while the oxygen is easily accounted for, whence comes the hydrogen? It is possible that sufficient quantities of this gas may be contained in the cells of the coke and given up so slowly as to diffuse with the oxygen in a close car, but escapes when open. It is more than probable that the free oxygen is bottled in the coke cells, and the harder and denser the cells the longer it is retained; but in the absence of further information upon the subject, such a theory is not entirely satisfactory. On this point the experience of other observers will be of great value to both the manufacturers and consumers of coke. While I cannot say that the sweating does not occur during the winter months, owing to the difference in atmospheric conditions, my attention has been directed more particularly to the hot and dry seasons. A remarkable feature observed is the fact that the moisture contained under such conditions seems to be in

excess of the capacity of the coke when simply immersed in water."

A New London Bridge.

The great new bridge across the Thames, opposite the Tower of London, is now nearly finished. It has been built upon the Bascule principle, in three spans, with two great masonry piers rising from the bed of the river. At this point the Thames is 940 feet broad and the depth of the water in mid-channel varies, according to the tides, from 30 feet to 35 feet 6 inches. At a distance of 270 feet from either bank, these great piers—204 feet in length and 100 feet broad—are built, rising from the foundations 27 feet below the river bed, excavated in caissons through the London clay. They cost, including staging, £110,122.

The masonry is of finely-jointed Cornish granite, lined internally with brickwork. Each pier contains a chamber in which works the heavily-weighted balance of the lower roadway leaf; each of these two leaves weigh little short of 1000 tons. When the two leaves, each 100 feet long, are closed, the lower roadway of the bridge is practicable for all kinds of traffic, pedestrian and wheeled, but the space of 30 feet, only, between the roadway and high water is insufficient to allow of masted vessels passing. It is to allow tall ships to pass that the draw-bridge principle comes into play. The hydraulic machinery placed at the Surrey side of the bridge is capable of raising the 2000 tons of iron and steel composing this movable roadway in two minutes, and it is confidently declared that the opening of the roadway, the passage of a ship and the closing again will take only five minutes.

Solidified Petroleum.

The method of making fuel bricks of crude petroleum adopted by Engineer Mastracci, of the Italian navy, is as follows: The bricks are of similar form and size to the coal briquettes extensively used in France and Germany. The mixture is made in the proportion of one liter of petroleum, ten per cent of rosin, 150 grams of powdered soap and 333 grams of caustic soda. The mixture is heated and stirred at the same time; solidification begins in about ten minutes, and the operation must then be carefully watched. If there is a tendency to remain liquid, a little more soda is added. The mixture is stirred until the mass becomes nearly solid. The thin paste is then poured into the molds, which are placed for 10 or 15 minutes in a drying stove. The briquettes are then cooled and are ready for use in a few hours.

Signor Mastracci recommends the addition of 20 per cent of wood sawdust and 20 per cent of clay or sand, which will make the briquettes cheaper and more solid. In trials made at Marseilles on several tug-boats the petroleum briquettes furnished about three times as much heat as coal briquettes of the same size. They were burned in the ordinary boiler furnace, without any special preparation, and gave out very little smoke, leaving also little or no ash. The advantages claimed for the petroleum briquettes for marine use are the absence of smoke and a large reduction in bulk of fuel which must be carried, as compared with coal, while the risks attending the carrying of liquid fuel are avoided.

To Strengthen Copper Pipe.

A method of strengthening copper steam pipes by means of coiled metal wire is described by Nabor Soliani. The practice is to serve the tubes over with one or more layers of closely laid metal wire, wound on under tension. Drawn tubes up to about eight inches in diameter are made out of copper sheets by brazing in the usual way, and are then wrapped round with a close spiral of copper or Delta metal wire. This method has been adopted in the Italian navy.

Electricity.

Nikola Tesla.

Perhaps the most daring of the experimenters of the latest decade of the nineteenth century is Nikola Tesla, who was unknown to the scientific world five or six years ago, but who to-day is regarded as a second Edison, and who has achieved more magnificent results than any half-dozen of his contemporaries combined.

To sum up his achievements in a few words is impossible, says *Paper and Press*. He has discovered, or, rather, demonstrated, the possibility of illumination without wires or globules in almost exact imitation of daylight. This lot he can vary to order, and although he has not been able to bring it to what he termed a commercial basis, he has advanced so far in the direction that comparatively little remains to be done before the public can buy daylight by the room instead of by the lamp or light. And this is but one of his marvels. He has produced a flame which does not consume and which gives out no heat whatever, and has thus laid the foundation for untold developments in every phase of electrical work. In the production of ozone by electricity he has also scored a distinct triumph. He has shown that nearly all sanitary problems can be solved by the aid of electricity, and he has also made immense strides in the direction of solving the problem of parceling out electrical force and enabling it to be applied to manual labor in every possible direction.

He was invited to visit London and explain his experiments on the very spot made immortal by Faraday. He went, and was received by the Royal Institution with due honors. The moment his fingers grasped his long glass tubes they glowed with a softened splendor, and when he waved them over his head they gleamed with a radiance which was described as weird, if not ghostly. He manufactured flames which appeared dangerous in the extreme, and then placed them in a wooden box, which was absolutely unaffected by them. He repeated these experiments, with several others, while the guest of the National Electric Convention in St. Louis, at the end of February, and he also explained the details somewhat more fully.

An Electric Lighthouse.

The present flash light at Fire Island, New York, is to be changed by the substitution of an electric light, the new light to have a strength of about 240,000,000-candle power, says the *Electric Review*. This will make it by far the most powerful light ever placed in a lighthouse tower. Congress has appropriated \$10,000 to change the light, and the Lighthouse Board will soon authorize the electric light to be put in. One of the largest lenses ever constructed has been recently purchased from France, and will be brought from Chicago, where it was on exhibition during the Fair. This lens is over nine feet in diameter, and was purchased ostensibly for the new light station being erected at Hog Island, Va., but the Board has decided to use it for Fire Island, and will transfer the lens now there to Hog Island.

The present light at Fire Island flashes at minute intervals, each flash being of five seconds duration. The new light will flash every five seconds, and will be less than a second in duration. The flashes will come with the rapidity of lightning, and will be so quick that bearing can be easily taken during intervals. The old light is visible under favorable conditions about 18 miles, but the engineer of the Lighthouse Board estimates that the powerful electric rays will be discernible fully 24 miles under similar conditions. By the aid of the new lens the light will be thrown on the heavens, and its re-

lection will be seen with ease by vessels approaching 100 miles away. The only light in existence which will approach it in power is the one off Havre, France, which can be seen reflected on the heavens 60 miles at sea. Its candle power is about 130,000,000. The great advantage of the new light will be its power to penetrate a fog. Ordinary oil lights can be seen a short distance only, but it is believed the new light at Fire Island will pierce the fogs and be visible ten miles at sea.

Electricity in Agriculture.

A bill has been introduced in Congress by Senator Pfeiffer, providing for the establishment of an experimental station for testing the use of electric power for farm implements and machinery, to be under the supervision of the Secretary of Agriculture, and an appropriation of \$10,000 is named for the first year's expenses in putting the plan into operation.

The value of experiments of this kind is not a matter of question to any one at all familiar with electrical work, says *Electricity*. As a means of propulsion for moving machinery, such as plows, mowers, reapers, etc., electricity would hardly be more adaptable than a windmill or a sail. We may assume that a 500-volt current would be necessary, and very few farms are equipped with electric power stations. But even with the necessary current supply, how is it to be adapted to the machines? The trolley is evidently out of the question, as it is hardly feasible to cover a farm with trolley wires close enough for plowing, and the storage battery is poorly adapted for running over plowed ground. In view of the fact that steam engines have failed in this work principally on account of the high cost, electricity, even if it could be applied, would be a still more expensive failure.

For running stationary machinery, such as thrashers, a motor may readily be used if the current is at hand, although a portable steam engine will probably be found very much cheaper.

The question is perfectly apparent in any particular case to almost any electrician, and there is no more necessity for government investigation of this subject than there is for a revision of the multiplication table.

Dry Batteries in Telephone Exchanges in Germany.

The openlog address of Herr von Hefner-Alteneck, president of the Elektrotechnische Verein, Berlin, dealt largely with telephony. He said:

"I note first that the magneto telephones, up to a recent date used as transmitters on many German telegraph lines, have been replaced by microphone instruments. Another improvement is the replacement of battery call bells by magnetos in the telephone service of the Berlin exchanges. I should likewise mention the substitution of dry batteries for fluid cells in connection with microphones, and that such cells have given great satisfaction. As you know, the administration has been carrying on exhaustive experiments with compound or bimetallic conductors, and, as I understand, with highly satisfactory results."

Marvelous Display in Texas.

Cuero, Texas, was treated lately to an electrical display such as has never been seen or heard in that section. It began with distant thunder, getting closer rapidly, and in less than five minutes there were heavy peals of thunder, and lightning flashes, and sparks or balls of fire are said to have descended within five feet of the ground and burst, making a loud report. The people were all frightened and are not anxious to have the same kind of a treat again.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assay; Examples of Dressing; The Melting in Crucibles; Scorching; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Crucible Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1889. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion; Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhard's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new, original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

Books on Working Ores.

By GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition on the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1890.

This rare book on the treatment of gold and silver are without quicksilver is liberally illustrated and crammed with full facts. It gives short and concise descriptions of various processes an apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3, coin, postage free. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages, octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by DEWEY PUBLISHING CO., 220 Market St., San Francisco.

THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS
1891. MORE THAN DOUBLE THIS CAPACITY with one-half less power and occupying less than one-half the space of any other concentrator. Built of Best Steel and Wrought Iron. Strong and Durable. Price \$375 f.o.b. Send for Catalogue and Testimonials. The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge. THE IMPROVED MACHINE HAS THE FOLLOWING MERITS: First—The improved belts, which consist of seven, are constructed and arranged so as to allow each belt to receive a portion of the pulp in such a manner as to relieve the machine of its load, thereby giving it twice the capacity of other concentrators, and enabling it to work from 12 to 15 tons of ore per day. Second—The machine equalizes the load by having several compartments, thereby working more regularly and with much less attention than is necessary to give other concentrators using wide belts. Each of the belts on this machine takes care of the pulp that is allotted to it—in this way preventing the pulp from running to the lower side of it, as is the case when a machine becomes out of level where wide belts are used. Third—The belts run on a perfect line, needing no adjustment to prevent their running from side to side, as in other concentrators. Fourth—The belt surfaces are improved by indentations and corrugations, causing the Concentrator to save fine sulphurets and quicksilver, and perform close work. Fifth—The belts have fluted or corrugated edges, to form an expanded top edge, which effectually prevents from cracking. Sixth—The feed arrangement is perfect. Seventh—The machine is constructed of iron, with steel crank-shaft self-oiling boxes, and everything made in the most thorough manner, enabling it to run with very little attention or wear.

GEO. E. WOODBURY, Manufacturer, 213 to 219 First Street, San Francisco, Cal.

Was awarded the Highest (Bronze Medal) Premium at Mechanics' Institute, 1890 and 1891. [copy.]
Eureka Tellurium Gold Mining Company, Redding, Cal., July 21, 1893.—Mr. Geo. E. Woodbury, 213 First St., San Francisco, Cal.—Dear Sir:—We take pleasure in stating to you that the two Ore Concentrators purchased from you last April are giving perfect satisfaction. They are simple, durable and effective, and we hereby conscientiously recommend the "Woodbury" pattern to all intending purchasers of Ore Concentrators. Yours truly,

[Signed] EUREKA TELLURIUM GOLD MINING CO., by GEO. O. JONES, Secretary.

PATENTED Aug. 13, 1890.

MINE BELL SIGNALS

ADOPTED, USED AND IN FORCE IN ACCORDANCE WITH STATE LAW.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12x36 INCHES, THE MINE BELL SIGNALS AND RULES provided for in the Voorhies Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth, so as to withstand dampness, for 50 cents a copy. MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

THE BAY STATE.—Enterprise Cor. Record: Sinking in the Bay State is progressing rapidly, and the contractors think that if no change occurs in the rock, they will make their 100 feet by the 1st of February. The bulkhead holds the water safe, and the sinking is comparatively dry. The Bay State is preparing to ship six tons of ore to the mining exhibit of the Midwinter Fair. There will be quite a lot of rock shipped from this district to the county exhibit, and there could be a lot more sent from the prospect shafts in the vicinity if the prospectors were able to pay freight on same to the railroad.

Butte.

GETTING READY FOR ORE.—Forbestown New Era, Dec. 29: Parties are at work upon the Mt. Hope mill, getting it ready for crushing ore. The mill is situated about four miles east of Forbestown. The mill will be almost entirely rebuilt, and will be operated by steam. The boilers and engine are on the ground. The ledge from which the ore to be crushed in the mill is to be taken has been worked before, but with the machinery then employed it could not be made to pay. The ore prospects well, and with the improved machinery by which it will be worked in the new mill there is no doubt but that it can be made to pay.

Faulkner & Bellingham are taking some excellent ore from their tunnel upon the Missouri mine, about a mile and a half west of Forbestown. They are in about 70 feet with their tunnel, and have a 20-foot ledge, which stands almost perpendicular. Several assays have been made of ore from this mine, one of which went as high as \$185 to the ton, and none under \$16 in gold. Experts are of the opinion that this mine is one of the best in the district, when everything is taken into consideration. A few days since a block was got down, the estimated weight of which was 2000 pounds. It was the intention of the owners of the mine to send it to the Midwinter Fair, but in the attempt to get it out of the tunnel it slipped from the truck, and fell in such a position that it could not be reloaded without breaking.

Calaveras.

GOON PROPERTY.—Angels Echo: The Gilman & Mercer mine, situated near Smith's Flat, is rapidly developing into a mine of great value. It is opened by a tunnel which is 50 or 60 feet below the surface. The vein or lode is nine feet in width, and carries a very large percentage of sulphurets which, it is said, will assay over \$1000 per ton. The mine is no doubt a splendid milling proposition. The present owners have not the means to develop the mine.

The Utica Mining Co. is engaged in running an open cut through Robert Rasmussen's lot, near the gas works. When the cut is completed a tunnel will be run from this point under the street to Chinatown. The tunnel, according to the survey, will be 14 feet below the level of the street. A flume will be built from the Matteson mine through the tunnel to the Stickle mill, the object being to convey the sulphurets from the mill to the works at the Matteson mine. The water now in Angels creek will pass through this tunnel.

Nevada.

AT NORTH BLOOMFIELD.—Herald, Dec. 29: The White Diamond quartz ledge, of which T. A. Fairweather is the locator, shows a fine prospect. The ledge is being worked, and all the extensions, north and south, are taken up. It is thought the White Diamond will make a mine.

J. Ostrom, too, has a good quartz claim. He picked up a nugget worth \$4.80 there the other day.

The Derbec drift gravel mine is looking pretty well, though only a day shift is worked—25 men in all.

T. A. Fairweather fell from a platform in the Derbec, last week, and fractured three ribs. He is recovering rapidly from the injury.

THE BELLEFONTAINE.—Herald: It looks as though the parties who bonded the Bellefontaine for \$25,000 might not come to time, and in view of recent developments the owners are willing they should not. If the mine is not sold as a whole, the company will soon put 25,000 shares of stock on the market, and the proceeds will be used in building a small mill. With a mill on the property, the owners could not make money faster than by working the mine themselves.

TWENTY STAMPS MORE.—At the California mine, Eureka district, 20 stamps will be put in next spring. The obstacles in the way of disposing of the property have all been overcome, and Col. Tozer is now free to make improvements and develop the mine.

MINA LOCATAN.—Telegraph, Dec. 28: A few days ago some parties in Grass Valley, headed by S. P. Dorsey, located some mining property bordering on the Grass Valley mining district, which is destined to become very valuable in the near future. They have named their claims the Texas, Tennessee and Louisiana. The district in which they are located has not been developed to any great extent, but the gentlemen who have now interested themselves in that section of the country will make lively times.

THE MURCHIE.—Transcript, Dec. 30: Two or three companies have of late been figuring on buying the Murchie mine. It is believed to be a good mine by many of the men who worked there at the time operations were suspended some years ago, and expert mining men who

have been here at different times to look at this mine all speak favorably of it. There are three ledges included in the company's ground, all of which, it is claimed, will pay if worked systematically.

RICH GRAVEL.—Transcript, Dec. 26: For the past few weeks the gravel in the Original Harmony has been steadily improving in quantity and quality, and now it is fully demonstrated that the owners have a big mine. On Saturday last a nine days' cleanup was made, which netted \$2200.

NEW HOISTING WORKS.—Transcript: Men have been set to work grading for the new hoisting works that are to be put up on the Merrifield mine by the Champion Company. The construction of the buildings will be pushed ahead as rapidly as the weather will permit.

NO SALE MADE.—B. N. Shoecraft appeared much amused when he heard that he had sold the Nevada City mine for \$100,000. He informed the Herald that he has once refused twice that sum for it, and that the man who wants the mine more than he does will have to pay what it is worth.

Placer.

PUMPS AT WOK.—Placer Herald: The pumps are gaining on the water in the Weske mine, near Michigan Bluff, and it is hoped to be able to commence taking out gravel early in the new year.

PUSHING WOK.—The Gold Ring Mining Co. at Green Valley, says the Colfax Sentinel, is pushing work on the mill. The weather has been much in their favor. They are finding some very rich gravel while grading for the mill site, and the channel is expected to show much better dirt.

MUSIC OF THE MONITOR.—Herald, Dec. 22: Hydranlicking was resumed in the Polar Star mine at Dutch Flat last Monday. Years ago Dutch Flat was one of the liveliest and most extensive hydraulic mining districts in the State; but the injunction era came and the mines in that camp ceased. But a new era has dawned, the result of wiser council, and a change is coming over the scene. Under certain conditions hydraulic mining may be resumed. So far as relates to the Polar Star, one of the big mines of that district, those conditions have been complied with, and under the direction of John Spaulding, the superintendent, the water was turned on again last Monday, and once again after years of patient waiting, and hoping against a condition that seemed almost hopeless, the music of the monitor is heard in that camp, and no orchestra ever had the exhilarating effect that the monitor's music has to the miner. This is the first hydraulic mine of consequence within Placer county to resume under the new order of things.

RESUMED WOK.—Placer Herald: Work was resumed again by the South Yuba Canal Company on the big new ditch which is to bring clear water to Auburn and materially increase the water supply of the entire foothill section of Placer county. The ditch is completed to a point not far from Colfax and it is there where the work has been resumed. The new ditch will cover the country around Colfax and much other land not covered by the present system. It will give to lower Placer a water supply for domestic, power and irrigating purposes not second to that of any other part of California.

Plumas.

TWO MINES TO START.—National Bulletin: On Tuesday morning early a force of men began the work of removing the hoisting works of the Loring & Leavitt mine to a position about 100 yards southeast of the Riverdale shaft on the Kellogg property, and on the line of the Elizabethtown gravel channel, north of Quincy. Both mines are now under the control of a New York mining man, who proposes to develop them. The work of removing and erecting the hoisting works will be pushed with all possible speed, so as to permit the sinking of the shaft to begin as soon as possible. It will probably be the first of February before the shaft can be started. The position of the new shaft will be such as to tap the channel near the center. It will drain and command a large stretch of the gold-bearing gravel deposits above. Parts of this that were mined years ago proved very rich, though the means and methods of working were respectively limited and inadequate.

TAIP TO THE MINES.—National Bulletin, Dec. 23: Last week the editor of this journal made a flying trip to Johnsville, Eureka Mills, Mohawk and Beckwith. Among the new enterprises to operate next year is the hydraulic mine owned by a Pittsburgh company, E. J. Sugden being the president and Pit Trayner the superintendent. The property is located only a few miles from Cromberg. During the past season the company did a great deal of work in fitting up the mine for operation. A reservoir and ditches were made, buildings erected, flumes put in and much other necessary work done. Mr. Trayner will soon begin the construction of such restraining dams as will be necessary to impound the debris, though the mine is so located that no damage to the lower country could possibly result from the operation of it.

During the past summer the Tefft mine has been worked on a small scale and with most flattering results. That this is a good property, the work of the past season has fully demonstrated. There is a large area of mining ground in this vicinity and those acquainted with it believe that it contains much treasure. Already Nevada capitalists are looking that way.

The town of Mohawk is quiet at the present time, yet during the past year much business has been done. During the winter season few of the small mines are worked, owing to the cold weather. In Mohawk valley and vicinity considerable gold is extracted annually by men

scattered here and there and mining in a small way. More than \$10,000 in "dust" has been shipped from that express office alone—shipments from the small mines referred to.

Since the big fire of a year ago Johnsville, owing to litigation as to the townsite and the unfavorable outlook at the Eureka mine, has not been rebuilt to the extent it would have been under other circumstances. However, it is probable that another year will witness more improvements. Greater confidence now prevails as to the future of that part of the county. Mining interests are looking up. Recent developments in the Plumas Eureka justify the belief that the old mine, which has produced millions in gold, will continue to yield large returns to the owners, consume vast amounts of produce and scatter its thousands among the people of the county. Few mines in the State have yielded larger returns during so long a period of time than the Plumas Eureka.

Contract work in the Jamsou mine continues. Messrs. White, Dunn and Smith, the contractors, are making good progress in the tunnel. The opening of spring will probably witness much greater activity about it. In the meantime development work will continue. Mr. Cheney, the superintendent, has gone to Shasta to look after property interests, but will return in February.

Shasta.

THIRTEEN TONS CRUSHED.—Democrat: Last week Peter Scherer crushed thirteen tons of ore from one of the mines in the Tellurium group that yielded \$28.50. This ore was taken from a new opening on the mine and was milled just as it came from a four-foot vein.

Siskiyou.

RICH DISTRICT.—Yreka Journal, Dec. 27: The quartz mine at Know Nothing creek, on the headwaters of Salmon river, has been taking out a great amount of rich quartz during the past season, and expect to do better every coming season as the claims are opened to better working advantage. This district bids fair to become one of the richest in the county, and with its development the adjoining creeks and gulches will be opened with good success by prospecting parties. The New river mines in Trinity county, on the opposite side of the ridge from Know Nothing creek, have also been yielding good returns during the past summer.

The Eastlick Bros. have been enabled to start up work at their hydraulic mine, Oro Fino, much earlier this season, by reason of the late rains furnishing a good supply of water in the ditches, with good prospect of continuance of water supply until midsummer.

The R. H. Campbell hydraulic mine at Quartz valley is also well supplied with water for starting operations, and will no doubt yield handsome returns, as extensive preparations were made during the past summer by drifting and other work to be ready for the winter season in good shape.

A Henley correspondent writes us that a porphyry dyke, ranging from 50 to 300 feet in width, has been discovered near that place in Cottonwood mining district. Its course has been traced for four miles, and it is soft and easily worked with a pick. It is full of small stringers of quartz which prospect exceedingly good. Mr. Legitt, of Medford, has a claim on this dyke, and Burleson & Rummel, Sullivan, Jones & Mitchell, and Call, Coleman & Co. also have claims. They say there is plenty of room for more claimants not afraid to handle the pick. One of the discoverers is so jubilant as to claim that he has found the long lost Rider Hidden mine, which parties have been hunting to find during the past fifteen years.

All the Klamath river miners will resume operations early in the spring, and they lament the losses sustained by the high freshets during the past few weeks.

The quartz mill at Judge Holcomb's mine on Salmon river will be started up this week in crushing quartz on hand, and he also has an arrastra testing a rich ledge in the same vicinity.

Trinity.

DITCH PROGRESS.—Journal, Dec. 30: The ditch of the LaGrange Hydraulic Gold Mining Co. is nearly ready to receive the water, the slides of earth occasioned by the last storm having been about all cleaned out. Thursday the water had been conveyed down from the head about one mile and by to-night (Saturday) the contractors will have passed over the worst part of the ditch with the water. The first four or five miles have been made difficult by the snow of the recent storms, but farther down the line this difficulty will not be encountered. If no bad weather interferes the water will be through to the mine in another week. The long tunnel on the east side of West Weaver creek was broken through Wednesday night and will be completed in a few days.

NEVADA.

Ferguson District.

TO START UP.—Pioche Record: The Hiko mill made a permanent start on Magnolia ore Tuesday morning in charge of Johnny Ferguson. Ten days hence we look for a good cleanup. The success of his enterprise means much for the immediate future of this district, as, if entirely successful, the mill will be open for custom ores from other claims in the district.

Red Canyon District.

GOON TWO-FOOT VEIN.—Enterprise, Dec. 28: Red Canyon is one of the most important mining districts in Douglas county. The ore there is gold-bearing, and very rich deposits have been discovered at intervals during the past 15 years. The amount of gold produced in that district is hard to estimate, for the reason that it was taken out exclusively by prospectors who were working their own claims and who kept the amount of the bullion produced a secret.

Last fall G. A. Fitzmier, of the City Bakery, who is sole owner of the Red Clond location in Red Canyon, employed two men to do the annual holding work on that location. These men cut into a vein two feet in width, a part of which shows high assay value per ton in gold. Next spring Mr. Fitzmier intends to take charge of the work of extracting and milling the ore. There is a five-stamp steam mill within a mile of the Red Clond which will be put in repair, and the ore extracted will be crushed in that mill.

ARIZONA.

RICH SILVER ORE STRIKE.—Prescott Journal: Geo. Leforse, from Groom creek, reports a rich strike by the Messrs. McCarty, in a silver-lead claim in that district. They have a foot vein of ore that runs 200 ounces silver per ton and about 60 per cent lead. Their shaft is about 45 feet deep, with this character of ore all the way down. Weckler & Morris have also made a great gold strike in the same district. They have a tunnel in on their ledge 50 feet, the ledge being four to five feet wide, and running from \$20 to \$100 gold per ton. The ore is free milling.

ANTIMONY FOUND.—It is reported from Magdalena that Thomas Yerkes has discovered an antimony mine nine miles from Santa Ana, Sonora. The assays that have been made are encouraging. The discoverer has sent several tons of the ore to smelting works in the United States to obtain practical results.

OREGON.

GOLD BUG DISTRICT.—Baker City Democrat, Dec. 25: A new camp christened Gold Bug district, is the latest to claim public recognition. The new camp is situated about seven miles west of Baker City. A few weeks ago Messrs. Hiram Maden, J. J. Nicholson, J. S. M. Foster, Harry Pring, Pete McAvoy and Edward Barker, British Columbia and Colorado Miners, commenced prospecting in the new district and the result of their labors has been most satisfactory.

J. S. M. Foster and Hiram Maden have four locations in a group, situated southwest of the Nelson placer mines. Messrs. Foster and Maden are at present developing the Annie May and Capitol mines and at a depth of 12 feet have a five-foot vein of ore, carrying free gold, specimens of which show particles of gold without the aid of a glass.

Messrs. J. J. Nicholson, Harry W. Pring, Albert Robinson and Hiram Maden have two claims south of the old Tom Paine property. They are running a tunnel on the pay streak and are now in 105 feet. The ore vein is about 15 inches in width and widening as work progresses.

Cavin Bros. and Sam Baisley have a fine showing in the Pocahontas mine, an extension of the old Tom Paine.

A mill erected by J. W. Sackett & Co. for custom work is in operation and is supplied with all the ore that the mill can handle and the results obtained thus far by mine owners have been very satisfactory.

In conversation yesterday, Mr. J. L. M. Foster, who has had many years' experience in Montana and Colorado, stated that the showing made in Gold Bug district eclipses anything he has ever seen in an undeveloped mining district and is more than enthusiastic over the future of the camp. How such a rich gold bearing district should have remained so long in obscurity is to him a mystery. But it can be accounted for on the hypothesis that in all these years the country has been simply run over by people who expected to pick up gold nuggets on top of ground and who when they discovered a prospect did development work with their mouth.

NEW CONCENTRATOR.—Ashland Tidings, Dec. 30: Mr. Staples, who is now in San Francisco, is expected to bring up with him on his return a concentrator for the mill on the Sterling ledge.

R. M. Garrett, Jack Garvin, Dr. Hirschlager and Crit Tolman came up from their mine on Williams creek last week, and report prospect work in progress with good results. Captain Ingalls, of Portland, another of the owners, visited the mine last week.

W. D. Anderson, a well-known miner and prospector, is in town this week from Sardine creek, and reports a good strike in one of his locations, about a mile from the Lindley quartz mill. The rock from a three-foot ledge assays \$17 in gold and \$6 1/2 silver.

It is rumored that an attempt is being made to compromise or settle the dispute for possession of the Hammersly mine at the head of Jump-off-Joe. Morton Lindley, of the Lucky Bart mine, and another man are said to be making the effort to bring Hammersly and Drew to an amicable agreement.

Will Q. Brown, of Riddle, reports that there is no prospect of anything being done at the nickel mines until spring, in any event. If the Chicago company is not prepared to commence active operations then, Mr. Brown believes another company will take hold of the business. There is a large quantity of nickel ore in that region not owned or controlled by the Chicago company, and the field will be open for a new enterprise if the old company doesn't begin to produce the metal.

MINING NOTES.—Jacksonville Times, Dec. 22: The Lucky Bart Mining Company have shut down their mill for the present, owing to the bad roads.

Ennis & Cameron are running on full time at their placer mines in Galice creek district, having an abundant supply of water.

Operations have been resumed at A. W. Sturges' placer mines in Jackass district, and a big run will doubtless be made there during the next few months.

Knott, Swinden and Donson of the Marland mine, in Kane creek district, have commenced a 500-foot tunnel on their property, and expect to do a great deal of work this season.

Coast Industrial Notes.

—Deputy Fish Commissioner Hunt, of California, has left Carson, Nev., with 90,000 ova of Eastern brook trout, to be placed in the water at Bear Valley, Cal.

—The Delamar Hotel, at Delamar, Idaho, was burned last week. The loss is \$25,000; insurance, \$5000. Several persons narrowly escaped being burned to death.

—The Idaho State Wagon Road Commission has let contracts aggregating \$114,500 for the construction of a system of roads to connect the northern and southern sections of the State.

—Mayor Pardee, of Oakland, has vetoed the ordinance prohibiting the use of gates on the local trains. The veto is made upon the grounds that the ordinance is illegal and the city would suffer defeat when the case was taken to the courts.

—The Metropolitan Electric Railroad Company in this city has petitioned the Board of Supervisors for one year's extension of time in order to complete the line to all points south and west of the intersection of Seventh avenue and I street. Financial stringency is alleged as the cause of delay in the completion of the road.

—The Siskiyou Mill & Lumber Co., says the *Dunsmuir News*, has the biggest sugar-pine board ever cut in the county, which they are about to ship to the Midwinter Fair for exhibition. The board is about 17 inches thick, 54 inches wide and 16 feet long. There is not a knot or flaw of any kind in it. It was cut by a hand-saw and is pure No. 1 sugar pine.

—The Mission-street bobtail cars, whose eastern terminus since last May has been at New Montgomery street, have begun running to the Oakland ferry. In the eight months which have elapsed since cars ran through, the old tracks have been displaced by substantial foundations and modern combination rails, preparatory to operating cars by electricity.

—T. H. Goodman, general passenger and ticket agent of the Southern Pacific has received a telegram from Tacoma, stating that the Canadian Pacific had put in a new rate of \$40 first-class and \$35 second class from Sound points to St. Paul, and a first-class rate of \$46 to Chicago. The rates are applicable by way of the Canadian Pacific and the "Soo" line.

—At a recent meeting of the Harbor Commissioners it was stated that the assignment of the San Francisco Bridge Company would not interfere with the work on the foundation of the new ferry depot, for which the company has the contract. Dredging is going on as usual, and the surety on the contract bond is sufficient to satisfy the board that there is no need for any proceeding toward a fresh contract.

—On the application of the creditors, George W. Hoadley, cashier of the National Bank of Arizona, has been appointed by the District Court to be receiver of the Phoenix (Ariz.) Electric Light and Power Company. The company was intimately connected with the defunct Hartford Bank. A re-organization is expected to bring the company out all right, as the franchise is very valuable and the assets are ample.

—The unemployed of San Francisco are to be given work. Business men, in a recent meeting, made a total subscription of \$14,000. This money is merely an earnest of a larger amount yet to come, and before many days, it is thought, a fund will be raised large enough to provide 3000 men with employment for the first three months of this year. They will be given \$1 a day and the employment will be in Golden Gate Park.

—The laying of the cable road for the extension of the Presidio and Ferries Railway Company's Sacramento-street line is completed with the exception of a single block on Sixth avenue, between B and C streets, and at several small places where crossings have yet to be put in. Work on the turntable at D street and Sixth avenue has been begun, and it is promised that the cable road will be ready for the cable cars by the 15th inst.

—Grapeland irrigation district, San Bernardino county, has run a tunnel 800 feet under the bed of the Lythe creek. Recently the workmen broke through the bedrock and struck a large stream of water and work had to be suspended until the tunnel can be protected from the wash of the stream. It is proposed to extend the works 150 feet further and tap the entire overflow of the stream, with which it is expected to irrigate the entire district.

—The San Diego City Council has adopted a plan which it is expected will solve the tramp problem. Work is to be given to all applicants in the improvement of

streets. Single men are to receive 75 cents per diem and heads of families \$1.25. All asking charity are to be put at work. If any refuse who are able to labor, they will be put in the chain-gang and worked separately, being paid no wages, but being provided with food and lodgings. Funds up to \$2000 per month will be expended for the relief of those out of work, but all the money is to be systematically applied to the improvement of the streets.

—The anxiety felt for some days in respect to affairs of the North American Navigation Company are at last set at rest, the requisite sum of \$100,000 having practically been raised by new subscriptions coming in and the old ones in many instances having been raised materially, while quite a number were doubled. The executive committee labored early and late to accomplish its purpose, with the result as related by one of its members.

—Mayor Carlson of San Diego, president of the San Diego, Yuma & Phoenix Railroad, has returned from Mexico, having secured the right of way through General Andreade's lands, and the most valuable concession granted by Mexico for years—the freedom from all taxes for thirty years. The road will run ninety miles in Mexican territory, and parallel to the big canal for forty miles. Eastern capitalists wired Carlson that the money was ready to build the road.

—Collector of Customs Howell, at Vancouver, B. C., has received a telegram from Sir Charles Hibbert Tupper, the Dominion Minister of Marine and Fisheries, instructing him to notify the sealers that it is likely the agreement with Russia regarding sealing will be renewed another year, the sealers consequently going into Russian waters on their own responsibility. The effect of this message has caused considerable comment in sealing circles, as a large number intended to go over to the Russian coast.

—The American Lumber Co., of Seattle, has carried a medal for three years, awarded by the Perkins Machine Company for the championship record of 156,000 shingles cut on a double block Perkins machine in a ten hours run. This record has been badly beaten by the crew of the Standard Mill Company, of Snohomish, Wash. The Snohomish boys recently cut 175,500 shingles on a Perkins double block machine in ten hours. This is certainly the championship record up to date. The crew of the McLeod mill at Edmonds, Wash., have a record of an average cut of 114,000 per day for twenty days.

—The report of Supervising Architect O'Rourke has been made public at Washington. It shows the following amounts expended and available on September 30, 1893: For the construction of public buildings on the Pacific Coast—San Francisco, \$193,768.82; Los Angeles, which has been completed, has still available \$128 88; Sacramento, \$4827. A site has been purchased for a building at Stockton, but no plans have yet been prepared. The appropriation for the building was \$75,000, of which there is yet available \$57,052.45. San Jose had available in September \$55,814 31. There is available on the building at Portland, Or., \$87,980.09, and none of the money appropriated for the Port Townsend (Wash.) building has been expended.

—It is stated on good authority that President Foster of the San Francisco and North Pacific Railroad has under serious considerations co-operation or amalgamation with a new Mendocino county railroad scheme. Under this plan the San Francisco and North Pacific Railroad would be extended from Ukiah to Eureka. There is at present a road twenty-five miles in length from Eureka southward, and the new road would connect with this. The scheme is not new and surveys have already been made from Eureka to Ukiah. The cost of construction of this road has been estimated at \$4,000,000. Humboldt county alone has offered a bonus of \$250,000. The scheme rests largely upon the result of the negotiations which are believed to be in progress between the Fort Bragg Lumber Company and the San Francisco and North Pacific Railroad. The railroad is anxious to carry the product of the Round Valley coal fields to San Francisco and also into the Sacramento valley. It may also offer to put the redwood of the Fort Bragg Company in San Francisco as cheaply as can the schooners.

Complimentary Samples.

Persons receiving this paper marked, are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

THE GRIFFIN MILL

The Only Perfect Pulverizer

OF
QUARTZ,
GOLD
OR SILVER
ORES,
PLUMBAGO,
PORTLAND
CEMENT,
OF
PHOSPHATE
ROCK,
FOUNDRY
FACINGS,
And All Other
Refractory
Substances.

Will work either wet or dry, and deliver a finished product. Capacity, 3 to 4 tons per hour on Phosphate Rock, 1½ to 2 tons per hour on Portland Cement, Quartz or Ores, depending on hardness of material to be pulverized and fineness of product. Grinds from 30 to 250 Mesh with equal facility.

NO JOURNALS IN GRINDING CHAMBER. BALL RIGID ON SHAFT HAVING DIRECT POSITIVE ACTION ON MATERIAL. MINIMUM POWER PRODUCES MAXIMUM AMOUNT OF PRODUCT. IT IS ABSOLUTELY GUARANTEED IN EVERY RESPECT, BOTH AS TO CONSTRUCTION AND CAPACITY. FIRST COST, WEAR, AND OPERATING EXPENSE MUCH LESS THAN STAMP MILLS. LARGE NUMBER OF MILLS IN USE ON DIFFERENT MATERIALS WITH POSITIVE SUCCESS IN EVERY INSTANCE.

Physical Features of the Mother Lode.

The two illustrations on this page are a continuance of the several views we have recently presented of mines and mills in Amador county, California. These are sample outcrops, such as are to be seen frequently along the mother lode. The upper plate shows a quartz outcrop at the Seaton mine, about a half mile north of the Gover. The lower plate shows an outcrop of greenstone forming the northeasterly termination of the Mayflower.

The topography, kind and amount of soil and vegetation on the mother lode are closely connected with the underlying rocks. The variations in the amount of erosion of different strata chiefly determine the topography, while its distinguishing features are governed by the strike, dip and faults of the strata. Vertical or steeply inclined rocks—either eruptive dikes or sedimentary strata—characterize the whole territory of the lode.

The four formations—granite, slate, serpentine and diabase—are each distinguished by a different surface and soil. The granite is characterized by a rolling surface and light, though fertile, soil. The serpentine, unless lying in a valley where it receives wash from other rocks, is uniformly distinguished by an almost barren surface, with little soil, no grass, and only a few stunted trees. Its rapidity of erosion is between that of the crystalline and the slaty rocks. The two formations to which the most important topographical features are due are the long, narrow bands of slates and the adjoining diabase dikes. The uniform conformability of these great dikes to the stratification of the sedimentary rocks, their hard and indestructible character, and their

juxtaposition with the soft, easily eroded slates, have given rise to those long, deep, narrow canyons leading down to each of the main rivers that cross the lode.

The black slates in their rapid erosion produce a light,

thin soil capable of supporting only growths of greasewood, manzanita and chaparral, and by this growth of brush they may be traced over the greater portion of their extent.

In Mariposa county only does the diabase occur in great amount—on the east side of the lode. There it forms the Mt. Bullion range. On the west several mountains and ranges are conspicuous features of this rock. Where its surface is not too rugged, it produces the best of soil.

It is stated that the Gem mine, at Wallace, Idaho, has again closed down because of the low price of lead and silver. About 50 men are retained, however, to clean up the ore in the chutes and on the floors and this will probably supply the concentrator for a week or two, after which the remainder will be discharged with the exception of 20 to 25 men, who will be kept to blast out a chamber on the lower level preparatory to sinking a shaft from that level at a distance of nearly 1500 feet from the mouth of the tunnel. The time has now come when further development of this great mine must result in changing it from what is generally known as a "tunnel mine" to a "shaft mine," as the reserves are largely worked out above the level of the lower tunnel. The *Spokane Review* thinks this must shortly be the fate of the Frisco, Bunker Hill and other important mines of the Cœur d'Alenes, provided that their future development is faithfully prosecuted. The greater elevation of such mines as the Mammoth, Standard, Morning, Granite and others similarly situated, will permit of their development for many years by the less expensive method of tunneling. None of these mines are able to work at a profit with silver at 68 cents and lead at \$3.20 per hundred.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Quartz Outcrop on the Mother Lode; Greenstone Outcrop on the Mother Lode, 17. Bracket Flume, Miocene Company, 21.
 EDITORIALS.—Physical Features of the Mother Lode; Miscellaneous, 17. The Rewards of Drift Mining; The Alta Company's Trouble; Miscellaneous, 18. Work of the Debris Commission; Miscellaneous, 19. The Official Report of the Olympia; Labor on the Comstock; Fire at the Idaho-Maryland Mine; The Nance Double-Acting Cornish Pileger; Miscellaneous, 20.
 MISCELLANEOUS.—Hydraulic Mining; Digging Gold on the Snake River, 21. The Red Point Drift Gravel Mine; Concerning Coal Mining Machinery; Tin Mining on the Malay Peninsula, 22. The Prospects of Gold; Cyanide in South Australia; The Arizona Big Bug District; Buying Mining Machinery; Big Hydraulic Mining Enterprise, 23. Colorado's Mineral Output; The Raber Amalgamator, 23. Coast Industrial Notes, 23. Sluicings; Foundry Notes, 19.
 SCIENTIFIC PROGRESS.—The Harvest Moon; Determination of Manganese in Manganese Bronze; Dust Over Buried Cities; Gaseous Theory of the Earth, 25.
 MECHANICAL PROGRESS.—Cyanide Potassium and Iron and Steel; To Pump Natural Gas from Indiana to Ohio; Experiments with Magnetic Concentration; New Furnace Lining; A Great Bridge, 26.
 USEFUL INFORMATION.—Uses of Cotton Seed Oil; How Long Will Japanese Coal Last? A New Annealing Furnace; Improved Air Brake; How to Catch Mice; How to Tell a Person's Age; Hardening Plaster, 28.
 ELECTRICITY.—A Chance for Inventors; Artesian Wells for Electric Lighting; New Electric Locomotive; Blackness of Lamp Bulbs; Electrocuting for Animals, 28.
 MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 29.
 THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 31.

CONTRARY to expectation, the miners of Slocan district, B. C., do not regard the probable changes in the lead tariff with unmixed satisfaction. They believe that the cheap Mexican ores will force the price of lead down to nothing, and the smelter charges, which at present are quite reasonable, will be increased materially. The Slocan ores are now in demand for fluxes, a condition which would not obtain in an era of free ore and importations from everywhere. The fact is, they say, that Slocan ores can very well afford to pay the present duty, because they are high grade, and yet they can't bear competition with ore from Mexico.

GRASS VALLEY will speedily recover from the blow inflicted by the fire at the Idaho-Maryland. It is announced that the work of reconstruction will begin immediately. New machinery will be installed, if the old is damaged beyond repair, and the water which will inevitably accumulate in the mine will be taken out as soon as possible. It is a serious matter for 225 men to be thrown out of employment. But partial compensation will be found in the employment of many men in the work of rebuilding; but if this is not satisfactory, complete consolation should be derived from contemplation of the escape of all the imprisoned miners without the loss of a single life. The matter might easily have been infinitely worse.

THE Debris Commissioners have ordered the temporary suspension of hydraulicicking at the Polar Star mine, Dutch Flat, Placer county. The inspectors found that the impounding dam was not accomplishing the purpose for which it was built. The water was carrying off too much sediment on account of the soft character of rock being worked. Operations are ordered suspended until the dam can be raised. It is possible that the action of the Commission in this case will assure the valley people that the Debris Commission is not an organization created to promote the interests of the miners more than the farmers. Its purpose is to allow the resumption of mining wherever practicable and without detriment to adverse interests. The Commission is doing its work faithfully and well.

VERY SERIOUS FAULT has been found with a newspaper in the Comstock because it published a statement that 800 men were employed in the mines and related industries. The total is something less than 600. It does no good either to conceal or exaggerate the truth about such matters. Misrepresentation is certain to prove a boomerang. It is not desired to offer any sort of inducement for miners and others to go to the Comstock seeking employment, and any publication leading to that end is bitterly resented by the already large list of unemployed.

The Rewards of Drift Mining.

One of the most valuable papers recently contributed to contemporaneous mining literature was read before the Technical Society in this city last week by Ross E. Browne, M. E. The subject was the "Red Point Drift Gravel Mine," and the paper was prepared by Charles F. Hoffman, M. E., superintendent of the mine. A fine illustration of economical management is afforded in the operation of this mine, the details of which are fully set forth by Mr. Hoffman. A full abstract appears on another page.

It takes a high order of engineering skill, coupled with accurate knowledge of geological phenomena, to locate a hidden ancient river bed with certainty, and it likewise requires ability of scarcely less pronounced description to develop it successfully and economically. It is true that very many of the river beds have been found to contain vast quantities of gold, and the mines have been profitable even when crude and expensive methods of development were employed. But often the gold is scattered widely and impartially through the cement, high pay streaks being infrequent, and the development of the mine must proceed on strictly business principles. The Red Point mine is a case in point. The average per carload for five years was \$2.20, the average expense of production, including ventilation, transportation, labor, materials and management, was \$1.64 per carload. If we deduct from this interest on the original investment—a vast amount that was expended before pay gravel was struck—we find the profit not at all incommensurate with the risk undergone. Drift mining is all prospecting until the channel is found. Machinery must be secured and placed in position, and long tunnels run—development by shaft being more or less infrequent—and often thousands of feet of dead work done, and months and even years of labor expended before the actual operation of the mine can be undertaken.

In the early days of drift mining the rewards were not always sufficient offsets for the risk. Knowledge was inadequate and experience primitive. But in the modern days of the industry the location of a channel has become an exact science, and few errors are made. The existence of a lava-capped auriferous channel can be determined with certainty, and its location can be ascertained with close approximation by the employment of engineering skill, geological knowledge and common sense. Russel M. Dunn, M. E., declares it possible to determine the following in advance of doing any underground work on the claim:

1. The approximate location of the line of the bed of the channel.
2. The approximate elevation of the bed at any desired point.
3. The location of inlets, outlets or breakouts, and a reasonable certainty of distinguishing between them.
4. If inlet, outlet, or breakout, the probable length of rim to be run through and the depth at which it must be penetrated.
5. If no inlet, outlet, or breakout, then the nearest point of the channel line to the surface for tunnel or shaft, as may be most desirable.
6. The determination of the size of the channel and the probable extent of its pay lead. This being of advantage in estimating the probability of yield sufficient to warrant the necessary outlay of capital in development.
7. The tunnel or shaft can be so located as to have the shortest possible length or depth with the greatest possible certainty of finding the channel, and of thereafter being permanently utilizable for working the mine.
8. The preceding make it possible to estimate in advance the probable expenditure that will be necessary to open up the mine, and to avoid any unnecessary expenditure, thus assuring the greatest possible economy both of opening and of working.

The pioneer history of drift mining in California is a record of miraculous successes and pyrotechnic failures; its recent record is in the highest sense creditable to the engineers and miners who have sought to eliminate from the industry the element of speculation and give it a basis of certainty. They have brought to the task experience, industry, technical learning and prudence. They have deduced certain formulæ from observed facts, and have applied them, with variations to suit local conditions, with the most satisfactory results. The risks of capital which invests in this class of mining property have been reduced to a minimum. It can be estimated with sufficient safety just what outlay will be required before returns are made. Just as few investments in this class of mining are now unremunerative as in any other branch of business; and the rewards are often very much greater.

ONE more abandoned mine in California has been redeemed from idleness and placed on the list of producers. From the Reward, in Nevada county, which was idle for many years, have just been taken an initial 100 tons of ore, which yielded \$23.50 per ton. The cost of mining was about \$6 per ton. When the mine is in operation and a mill in place, more economical methods can be applied, and the Reward will be a permanent dividend-payer. There are many other mines in California with which the same thing may be done.

The Alta Company's Troubles.

The affairs of the Alta Mining Company are about to be ventilated in the courts. They abound in disclosures which contain startling charges of mismanagement and fraud, through which it is alleged the stockholders were mulcted in the sum of \$300,000. Papers have been prepared for a suit for accounting by certain shareholders against Treasurer Charles Derby and five Boards of Directors. The complaint is based on a report made by Expert George W. Reynolds, who was engaged for this duty by the new President, John Landers, and his co-directors. The management of the mine and its correlative company, the American Milling Company, was for years centered in the late Seth Cook, aided by his lieutenant, Charles Derby. George R. B. Hayes, attorney retained by the Directors, makes the following statement: "Reynolds' report shows that Cook was indebted to the company in \$70,000 for moneys which he drew and charged to himself. So lax was the management of the company afterward that no claim for this sum was presented against his estate, which was valuable. The estate is now settled up and divided among the heirs, so that this sum is hopelessly lost.

"The sum taken from the company in coin, as shown by the expert's report, will probably reach \$300,000. This does not include losses by a fraudulent lease. High salaries were paid out of all proportion to the labor performed, and entirely unauthorized by the by-laws.

"Cook and his associates organized among themselves a milling and mining company, and as officers of the Alta Company leased the mine to the new corporation for a nominal sum. It was a very close corporation. Cook let some of his directors into it without their knowledge. One director, whom I can name, when he was tendered the first dividend from the new enterprise remarked, 'I own no stock in that company, and this money isn't mine.' He was told to take the dividend and say no more about it. He obeyed orders. Until some of the men who came in for a share of the profits are placed on the witness-stand the amount thus diverted from the mine cannot be known.

"Then there is a big shortage in the bullion output. The books of the company show that the shipments from the mine were largely in excess of the amount received and accounted for by the San Francisco office.

"Derby succeeded Cook as general manager of the concern, and by some 'hocus-pocus' transferred the \$70,000 indebtedness to himself. This he increased to \$80,000."

Answering an inquiry as to the probability of the stockholders being able to recover any considerable part of the funds and bullion, Mr. Hayes said it was slim. Derby has a ranch in Nevada, but it is incumbered by a mortgage.

"Still he may have stowed some money away," remarked the lawyer, "which the company could get hold of. The directors are individually responsible for the losses, whether they are participis criminis or only guilty of gross negligence. There will be no trouble in proving that they were guilty of the last charge. The estate of Cook now being free from attack, I question whether the combined possessions of four or five Boards of Directors will suffice to make good the actual losses to stockholders by mismanagement and worse, even if judgment can be obtained against them."

Death of John H. Dall.

John H. Dall of this city, in former years widely known throughout California and Nevada in connection with mining affairs, died at his rooms in the Palace Hotel on Tuesday last, aged 75 years. The later generation of miners knew little of Mr. Dall, but old-timers will recall his connection with operations on the Comstock, and his great reducing establishment at Franktown, in Washoe valley. He was among the earliest of the Argonauts, and the large heart and the open ways of California's golden age never ceased to be reflected in his life and manners. Finely endowed with native sense, rich in the primary elements of manhood, strong in energy, sincere, brave and kind, John Dall was, as he deserved to be, ever universally respected; and to those who knew him well, he was very dear. His death came in the order of nature, in the fullness of years and after his life's work had been manfully done. It is noble thus to live; it is blessed thus to die.

THE Debris Commission has issued a permit to the Green Mountain mine, Mokelumne Hill, to resume hydraulicicking. An impounding dam has been constructed, as required.

THE Midwinter Fair will be formally opened Saturday, January 27, 1894.

Work of the Debris Commission.

The records of the California Debris Commission up to this time show that thirty-seven hydraulic mines have made application to mine under the Caminetti Act, ten have been granted licenses, and none have been formally rejected. Besides these a considerable number are going ahead with the construction of dams, which, if built according to plans submitted to and approved by the Commission, will insure the issuance of a permit. There is at present no good reason to believe that nearly if not quite all the mines in the appended list will not be in successful operation during the present year. The Commission has proceeded with its work cautiously, but on the whole wisely and satisfactorily; and it is undeniable that the Caminetti Act is day by day gaining strength with the miners.

The formalities through which it was necessary to go were for some time matters of objection to miners; but they are after all easy to comply with. The expense is light, and the applicants are assured of a fair and impartial hearing.

It has been stated that the mines which it was possible to operate under the law were all small, and that none of the large would resume, but it is obvious from the following that large as well as small mines secure the benefits of the Act. Several mines with impounding dams of considerable capacity have been allowed to start, and the list includes others of large size, which will doubtless be allowed to resume.

The Debris Commission has been actively at work since July, but its first public session was as late as September 4th. In the four months since then it has performed the bulk of its work. Under all the circumstances the results are satisfactory and full of promise for the future. Undoubtedly a great deal will be done during 1894, as it may be expected that many more mines will make application during the year.

The list of mines which have applied, with other information of interest, is appended:

Kelly Hill mine, Butte county; owned by Mooser & Boyd of San Francisco; dam of rock, brush and earth; capacity, 200,000 cubic yards; license granted ———, 1893.

Farrel mine, Nevada county; owned by the Eureka Lake and Yuba Canal Company (Consolidated) of Nevada City; dam of earth and logs; capacity, 212,000 yards; license granted September 8, 1893.

Omsa mine, Nevada county; owned by N. C. Tully of Stockton; dam 80 feet high in Scotchman creek; capacity, 1,000,000 yards.

Richmond Hill and Saw Pit Flat mine, Plumas county; owned by the Good Hope Mining Company of Oakland; rock dam in Onion Valley creek.

Brandy City mine, Sierra county; owned by A. Steinhager of San Francisco; brush and earth dam across mouth of old hydraulic pit; capacity 1,940,000 yards.

Blue Nose mine, Plumas county; owned by B. Below of Oakland; stone dam in Hopkins creek; capacity 50,000 yards.

Blue Gravel mine, Yuba county; owned by the Excelsior Water and Mining Company of Smartsville; old hydraulic pit tunnel stopped with rock; capacity 2,885,000 yards; license granted October 12, 1893.

Illinois Gold Gravel mine, Plumas county; owned by H. Buckley and Louis L. Hillman of La Porte; old hydraulic pit tunnels stopped with rock; capacity 35,000 yards.

New York Gold Gravel mine, Sierra county; owned by Westall & Hughes of Sierra City; brush, log and earth dam in Howard creek; spillway in creek; license granted December 5, 1893.

Corbiere & Bean mine, Butte county; owned by Corbiere & Bean of Clipper Mills, Yuba county; rock dams ten feet high in Hampshire creek; capacity 2000 yards; license granted November 20, 1893.

Phoenix Gold Gravel mine, Sierra county; owned by W. A. & M. E. Schofield of Hepsidam; dam in Whisky creek and north fork of Skate creek.

Eureka Mining Company, Downieville, Sierra county; dam of timber in Sawmill ravine.

Craycroft hill placer mining claim, Sierra county; owned by the Craycroft Mining Company; dams of timber in Hughes and Davidson ravines.

Excelsior hydraulic mining claim, Sierra county; owned by Excelsior Mining Company; dams of timber in Eagle Gulch and Smith's Flat.

Spanish Ranch, Plumas county; owned by W. C. Ralston of San Francisco; dam of timber in Spanish creek; spillways in old hydraulic pit; capacity 4,900,000 yards.

Polar Star mine; owned by John Spaulding of Dutch Flat; stone and gravel dam in Little Bear river; capacity, 605,000 yards; license granted December 13, 1893.

A Denmire dam, Sierra county; owned by A. Denmire; dam in dry ravine; capacity, 3100 yards.

Nevada mine, Sierra county; owned by Geo. W. Cox of Table Rock; dam on north bench of Slate creek; capacity, 6000 yards.

'54 Flat mine, Amador county; owned by '54 Flat Mining Company of Sutter creek; brush dam in ravine.

Red Hill mine, Shasta county; owned by Nathan Gardner of Ono; five dams in gulch; capacity, 900,000 yards.

Badger mine, Shasta county; owned by W. R. Stewart of Igo; dam on flat ground; license granted January 2, 1894.

First Chance mine, Sierra county; owned by Frank E. Barberio of Sierra City; bowlder, log and brush dam in

Howard creek; capacity, 8630 yards; license granted January 2, 1894.

Tannery Ravine mine, Yuba county; owned by W. R. Reed of Brownsville; log and brush dam in ravine; capacity, 4000 yards.

Mateos mine, Sierra county; owned by Manuel Mateos of Sierra City.

Davis mine, Sierra county; owned by Joseph Davis of Sierra City; license granted January 2, 1894.

Christmas Hill mine, Placer county; owned by McKinstry & Gilbert of Butcher ranch.

Walker mine, Shasta county; owned by Alonzo Engle and Frank Walker of Igo; ore, rock and four brush dams in Pomeroy creek.

North Star mine, Calaveras county; owned by McGuire & Havens of San Francisco; dams in gulch.

Hustler mine, Nevada county; owned by Joseph Hustler of Patterson; existing drain in Kilroy creek; capacity, 210,000 yards.

Green Mountain mine, Calaveras county; owned by J. W. Smith of Oakland; brush dam; capacity, 170,000 yards; license granted January 8, 1894.

Noonday mine, Sierra county; owned by John Egbert of Sierra City.

Pomeroy mine, Shasta county; owned by John McGrew and Alonzo Engle of Igo; rock dam in Pomeroy gulch.

Union mine, Plumas county; owned by Daniel W. Albert of Brownsville, Yuba county; rock and brush dam.

Welch placer mine, Sacramento county; owned by Columbia Gold Mining Company of Michigan Bar; stone dam; capacity, 300,000 yards.

French Corral mine, Nevada county; owned by the Kate Hayes Mining Company of San Francisco.

Manzanita mine, Nevada county; owned by the Kate Hayes Mining Company of San Francisco.

Campo mine, Yuba county; owned by Tonatino Campo of Brownsville; rock dam.

Slickens.

SPOKANE WANTS A SMELTER.

A new camp, christened Gold Bug district, is the latest to claim public recognition. The new camp is situated about seven miles west of Baker City, Or.

MINING ASSESSMENTS falling delinquent in January amount to \$151,840, of which Nevada mines call for \$136,340, California mines \$5500 and Mexican mines \$10,000.

It has been definitely decided that Idaho will make no exhibit at the Midwinter Fair. There are no funds available, and it is impracticable to secure private subscriptions in sufficient amounts.

THE Miller and Holmes Mining Company invites proposals for sinking their shaft on the property of the company at Quartz mountain, Tuolumne county, to a further depth of 100 or 200 feet. E. A. Stent is superintendent.

THE big Butte & Boston Company at Butte, Montana, is now working ten per cent more men than were ever before on its pay roll, and there is no doubt whatever that the present year will witness no diminution of its force.

A BITTAR war between the union and non-union men at Deadwood has begun. Three hundred members of the Union drove 130 "scabs" from the mine of the South Dakota Mining Company, on Anna creek, to Deadwood. Further trouble is expected.

THE Tidings, at Grass Valley has been leased to A. B. Champion and James C. Tyrrell. Mr. Champion has for several years been editor of the Tidings, and is an excellent newspaper man. Mr. Tyrrell is also well known in Nevada county as a newspaper man.

THE Occidental Aluminum Company has been incorporated. Principal place of business, San Francisco. Capital stock, \$500,000, with Albert H. Statham, W. S. Barton, W. J. McFarland, San Francisco, M. T. Cavanaugh and J. E. Norris of Eureka, Nev., as directors.

IN 1893, 78 mining assessments amounting to \$2,196,280, were levied against 81 assessments, amounting to \$2,566,320, in 1892. Of this year's assessments California mines want \$253,000, Nevada mines \$1,828,280, Arizona mines \$45,000, South Dakota mines \$50,000 and Mexican mines \$20,000.

SEVERAL Colorado towns have recently bid \$50,000 and over for the Corbett-Mitchell fight. In California it is a matter of most sacred conviction that Corbett is a 100-stamp battery in a mill. Who is the Munchausen, anyway, that has been libeling Colorado with his idle talk about hard times?

THE Yellow Jacket mine, in Lemhi county, Idaho, has under consideration a project to put in a 100-stamp mill in the place of its present one of 10 stamps. The Yellow Jacket is a free-milling ore with an ore seam running from 40 to 50 feet in width. The retorts are disposed of at the Denver branch mint.

THE Providence Gold Mining Company at Nevada City has filed articles of incorporation with the Secretary of State. The principal place of business is at San Francisco. The capital stock is placed at \$250,000, and Joseph Butzenbach, Peter Tautphaus, E. F. Liebrich, F. Boeckman and W. H. Wideman are directors.

It may not be amiss to call attention to the fact that the period within which notices must be filed of intention to take advantage of the assessment suspension law expired December 31, 1893, and that those claims upon which assessment work was not performed in 1893 are subject to relocation, provided no such notice was filed.

"JIM" WARDNER, from whom the town in Idaho was named, has arrived at Johannesburg, South Africa. He writes back that he has met John Hays Hammond, S. B. Connor and U. C. Clement. Clement is managing the Primrose mine; has 1800 colored men working for him and 200 whites. The Primrose paid a \$50,000 dividend in October.

MERRITT BAOS, Duluth capitalists, have bonded 2500 acres of placer ground along the Snaks river, near Grand View, Idaho, owned by Joseph M. McAfee and others, for in the neighborhood of \$100,000. The intention is to at once put in extensive machinery and develop the property vigorously. It

is said, with the machinery it is proposed to purchase, the total investment will aggregate over \$200,000.

THE stockholders of the Eureka Tellurium Gold Mining Company (Shasta county) met on the first of the month and elected as directors: E. A. Zoellin, F. B. Simonds, Philip Scherer and Peter Scherer, Redding, and S. W. Powell, E. C. Selfridge and C. A. Taber of San Francisco and Oakland. The directors then met and elected P. Scherer, president; C. W. Taber, vice-president; G. C. Jones, secretary, and the Bank of Northern California, treasurer. P. Scherer will continue as manager.

THE annual meeting of the San Francisco Stock and Exchange Board was held January 8th. Colonel William Edwards was elected president. Colonel Edwards last year served as vice-president. A. F. Coffin, the president last year, retires. A. B. Ruggles was elected vice-president. The other officers were unchanged, O. V. Walker being elected chairman, Geo. T. Marye treasurer, and F. W. Hadley secretary. The following Committee on Membership was elected: Geo. C. Hickox, James Paterson, H. H. Shinn, J. E. Dyer, Chas. D. Laing, J. R. Fitch and Charles H. Stoutenborough.

CAPTAIN O'BRIEN states that if the tariff on quicksilver is removed the New Almaden mines will have to shut down, as it will be impossible to compete with the European product. Even with the present duty on quicksilver it will be possible only to employ the men half-time during the winter owing to the general depression, but if the duty is removed altogether all the miners will be reduced to absolute want, with no means to provide for the support of their families.

PETER SMITH of Vancouver, B. C., has invented a mineral locating machine that fairly distances the divining rod as a finder of treasure. According to the highly lucid accounts received from Vancouver, "it resembles a wooden box with a tin fog-horn sticking through a hole in one side and suspended from a string within the box." Thirty dollars in silver was the other day buried near town, and the machine guided Smith—so we are told—to within 600 yards of the treasure. It was getting dark, and his friends then steered him to within 200 yards. The machine made a singular noise, and after a variety of maneuvers the silver was finally successfully located.

THE San Francisco Call has a very able editorial on the "Mining Product" of the United States, based on the recent statement of the Director of the Mint of the output for 1892. Unfortunately the Call assumes that the figures are for 1893, and rejoices that the industry is in such healthy condition, "notwithstanding the alleged disturbance in the silver mining industry caused by the silver controversy." Returns already at hand show that the silver agitation did have a tremendous effect on the silver mines, and that silver, lead and copper will show a heavy falling off. The year 1893 was not a banner year for these branches of the mining industry.

THE Treasury Department presents a table showing the monetary systems and approximates of stocks and money in the aggregate and per capita in the principal countries of the world. The list is:

Belgium.....	\$36 81	Germany.....	\$18 56
France.....	26 70	Portugal.....	21 06
Australia.....	26 05	Egypt.....	19 85
United States.....	26 02	South American States.....	19 67
Netherlands.....	24 34	Canada.....	10 00
China, all in silver.....	1 80	Cuba.....	12 31
Roumania.....	4 60	Italy.....	9 59
Servia.....	4 27	Switzerland.....	14 48
Sweden.....	2 71	Greece.....	12 22
Turkey.....	2 39	Spain.....	17 14
Central American States.....	3 78	Austria-Hungary.....	9 59
Japan.....	4 00	Norway.....	6 60
India.....	3 44	Denmark.....	11 72
Hayti.....	4 90	Russia.....	8 17
United Kingdom.....	20 44	Mexico.....	5 00

Since the statement was tabulated the United States has decreased to \$25.55. The table puts the stock of gold money at \$3,901,900,000; silver, \$3,931,100,000; uncovered paper money, \$2,700,000,000.

Foundry Notes.

THOMAS MCGLEW is at French Gulch, Madera county, putting in three concentrators at the mill of Spencer & Sharp.

THE 13-inch gun recently completed for the battleship Oregon at the Washington Navy Yard is the largest that is made in this country, and there are not many more that will be made of this size. It requires a charge of 550 pounds of powder and throws a shell weighing 1100 pounds a distance of 13 miles at the extreme elevation. At point-blank range it will penetrate 26 inches of solid steel. The gun in its finished state weighs 65 tons, but when mounted it can be moved throughout its extreme range with the pressure of a single hand. The steel of which the gun is made is known as gun steel and is the very toughest that can be produced. The mountings are from the Bethlehem Iron Works and will have to undergo inspection by a rigid board of army experts before they are accepted.

THE Joshua Hendy Machine Works has constructed and is proceeding with the erection in the Mechanical Arts building, at the grounds of the Midwinter Exposition, a five-stamp quartz mill which will be complete with all of the latest improved accessories of a Hercules rock breaker, Challenge ore feeder, Triumph concentrator, silver-plated plates, etc., and which is intended for practical operation upon such gold-bearing quartz ores as may be offered for crushing and amalgamating during the continuance of the exposition. They will also place on exhibition in conjunction with the above, a full line of their specialties of hydraulic mining machinery, comprising hydraulic gravel elevators, giants, water gates, pipe, air valves, etc., and, as well, horse whips, ore buckets, mining cars and such other paraphernalia as is essential to the proper conduct of enterprises involving the mining and milling of quartz ores and mining by the hydraulic system. They will also exhibit another of their specialties of lap-welded wrought-iron tubing, coupled with patent lead-lined couplings, for use as water pipe for irrigating, farm, dairy and other purposes, and will also place in operation a Russell automatic and an Ore & Sombower engine as power for certain departments of the exposition, for which they are agents. We are informed that these works were awarded premiums for exhibits at the Columbian International Exposition at Chicago, of ore feeders, Triumph concentrators, hydraulic gravel elevators, giants, etc.

The Official Report on the Olympia.

The government trial board has passed judgment on the cruiser Olympia, on her recent performance in Santa Barbara channel. She is officially credited with 21 686 knots, or 1.686 knots above requirements. The bonus to the builders will be \$300,000. The report of the trial board is complete in all essential particulars, but there are minor matters which must be passed on when the cruiser is fully completed and equipped, which will not be for several months.

The plans and specifications have been more than complied with in every point of machinery, speed, horse-power and coal consumption. From the report of the trial board, it appears that at the beginning of the trial the draught forward was 19 feet 7 inches, and aft it was 22.2. Coal consumption during the run reduced it to an even 19 feet forward, after the trial, without any change aft, giving a mean draught during the trial of 20.85. The mean displacement during the run amounted to 5570 tons, when only 5500 was called for by the contract.

The required pressure test was 160 pounds; at the boilers 166.53 was shown; at the starboard engine's steam chest the register was 166.75, and at the port engine's, 164.83.

On a requirement of 16,000 the main engines' indicated horse-power was as follows: Starboard, H. P. 2001; 1st, I. P. 3097.3; L. P. 3198.5; total, 8297.6; port, H. P. 1903.2; 1st, I. P. 3185.6; L. P. 3463.4; total, 8552.2; grand total for main engines, 16,849.8. The collective horse-power of the main and auxiliary engines operated during the trial amounted to 17,313.08.

Under these conditions of steam and power the furnaces ate up 39 937 5 pounds of coal per hour during the run; the starboard engine made 139 98 revolutions per minute, and the port 138.53; the starboard blower revolved 470 times per minute in creating forced draft, and the port blower 475 times. The slip of the twin propellers proved nearly as diversified as the performance of the starboard and port engines. Based on the mean pitch, the slip of the starboard wheel was 17.4 per cent of its own speed, and on the final pitch 21.50 per cent. Through the port screw the slip was 16.5 per cent on the mean pitch and 20.6 per cent on the final pitch.

It will take from seven to eight months to put the finishing touches on the Olympia so that she can be declared in commission.

Labor on the Comstock.

The total number of men now employed on the Comstock, including mines, mills, the Sutro tunnel, and the railroad, light and water companies, is 528. A controversy over the matter recently arose in Virginia City, and the *Chronicle* went to the trouble to ascertain the facts. The monthly payroll is taken as the basis of estimate, superintendents and office clerks being excluded. The payroll for the month of December shows that \$60,844.25 was expended for labor done during the month by the mines, the water and gas companies, the Nevada mill and the river mills. The share paid by the mines was \$47,844.25. The payroll of each mine is from the sworn statement of the secretaries and is authentic and reliable. There were 31 days in last month, and taking the average wage per day at \$4, the sum shows 386 men all told employed by the mines above and below ground, exclusive of superintendents and office clerks.

In order to ascertain the number of men employed underground, the Con. Cal. & Va. mine, the leading mine on the lode, may be taken as a basis of estimation. In the mines which employ the most labor there are generally more underground employees than top men; in the smaller mines the reverse is true. According to figures taken from the company's books by Chief Clerk Lowell, there are 97 employees above and below ground at both workings of the Con. Cal. & Va. mine. Of this number 52 are employed underground and 45 above. The division is almost equal. In addition to this there are 12 men employed underground by the West Consolidated Milling Company, making the total number of employees of the two companies 109. It has been stated that there are 170 employees in the Con. Cal. & Virginia. This is a mistake.

The proportions leaning the other way in the smaller mines divide the above and underground employees about equally. This being the case, it is easy to estimate the number of the latter from the payroll. The half of \$47,844.25 is \$23,922.12. The average wage underground is over \$4. Estimated at \$4 there are 193 underground employees on the Comstock. If the estimate is made at 60 per cent instead of 50 per cent, the number is brought up to 231. This is the outside number that can be estimated from the payroll, and from the cold figures furnished by the leading mining company on the Comstock.

Figures from the railroad company show about 25 men

employed between Virginia and the Mound House at an average of \$4 per day. There are about a dozen men employed on the Sutro tunnel. At \$4 per day, the light, water and mill companies employ about 103 men, as shown by their estimated payrolls, which are at top figures. The total number of men employed by the mines, mills, the Sutro tunnel, and the railroad, light and water companies, at the outside, is therefore about 528.

Fire at the Idaho-Maryland Mine.

The hoisting works at the Idaho-Maryland mine, at Grass Valley, California, were totally destroyed by fire Tuesday night, January 9th. The loss is about \$60,000; insurance in all surface works, \$32,000.

The fire was discovered about nine o'clock. The flames burned rapidly, and there ensued a scene of anxiety and consternation such as has never been witnessed in Grass Valley before. Hundreds of people rushed to the scene of the conflagration. Mothers, wives, sisters and brothers went out to the mine to get tidings of those who were working away down in the depths.

There were about 80 men in the bowels of the earth, and for a time it seemed as though they would all perish. The flames from the immense hoisting works were roaring and crackling, and gas was coming up from the old pump shaft, and then it seemed as though the men beneath the surface would surely meet a terrible death.

Three or four brave miners from above, who had assembled, went down the air shaft to warn the men below that the hoisting works were on fire, and told them to run for their lives. The utmost order and coolness seemed to take possession of the men underground, and with the precision of soldiers they made their way to the air shaft.

After a lapse of about an hour and a half, during which there was an age of agony on the surface, a mighty shout went up from hundreds of throats. The shout was one of joy, and fairly shook the surrounding hills. The first man had come out of the shaft. He announced that all were safe below. Women ceased their weeping and men regained their composure when they knew that all was well below.

Slowly and surely the men climbed the perpendicular ladder for the distance of nearly 2000 feet, and got to the surface almost exhausted. The hoisting works were burned to the ground, and the splendid machinery contained therein is ruined. It is supposed that the fire originated in the dryhouse, which is partitioned off the hoisting works.

The work of clearing away the debris has already begun. To what extent the machinery is injured will be known tomorrow. The work of replacing the defective machinery and the erection of hoisting works will be prosecuted as fast as possible, and if the necessary lumber can be procured and severe weather does not interfere, everything will be in good working order in about 60 days. Meanwhile, about 225 men are thrown out of employment, and the majority of them must remain idle until the work of reconstruction is ended. The shaft is not injured below a depth of 20 feet, so no time will be lost in reopening it. The old pump is forcing water from the 1000-foot level, but below that depth it cannot be handled, and the bottom of the mine will consequently fill up. It is the current belief that the burning up of the mine's plant will delay the transferring of the property to the Maryland Company several months.

The formal opening of the Colorado Gold Mine at the Midwinter Fair took place last Wednesday with appropriate ceremonies. The entire press of San Francisco had been invited to be present and many responded. Addresses were made by W. S. Chapman, W. C. Ralston and S. K. Thornton of this city and by William Keast, R. V. Robertson and others of the gold mine. The chief feature of the exhibit is a cross-sectional view of a mine in full operation with surface works, including hoisting works, mill, whim and ropeway. The working model is from the Saratoga mine, Gilpin county, Colorado, and is very ingenious. Other things are a tunnel and a shaft with a hoist. The various appliances for the working of a mine are fully displayed, so that a very complete idea of mining operations is given.

The Kennedy mine, Amador county, which in 1892 held the belt as the largest producing mine in California, was surpassed during 1893 by the Utica, in Calaveras county. The exact figures for the Utica are not yet obtainable, but it is known that for three months the production was close onto \$500,000; and in December alone the output was upwards of \$200,000. The Kennedy, in 1892, yielded \$443,000. During the year just passed this record was considerably surpassed, the total being \$640,000, of which \$480,000 was paid out in dividends. It is evident from these things that the mines of California are on the up-grade. The Utica is a particularly fine example of what has been done with an abandoned mine; and what has been done can be done.

The Nance Double-Acting Cornish Plunger.

The Cornish double-acting pump patented by Wm. Nance, of Grass Valley, and in operation there for about a year, presents a variation of the established system that will be of interest. The following description is furnished by Mr. Nance:

"This pump being double acting, it is evident that it lifts the column of water on the up-stroke and forces it on the down-stroke, producing a continuous discharge of water, instead of an intermittent discharge on the down-stroke only. The pump, column and main rod are only half the size of the old pump for raising the same quantity of water. The essential difference in the rod is that it is strengthened by two iron plates the whole length of the rod instead of plates on the joints only, which enables the rod to lift twice the weight of the column of water on the up-stroke, whilst on the down-stroke it is only just heavy enough to force the column of water, so that the weight of water lifted on the up-stroke is the same as in the old pump for the same quantity of water, only it is done with a rod half the weight and size. In fact, it may be considerably less than half the size, being governed by the thickness of the plates; but it must be half the weight. The engine is balanced in precisely the same way as it now is. The importance of this great reduction in the weight of the rod will be easily appreciated, especially when you consider the weight of a 12-inch rod 2000 feet long is 50 tons, exclusive of iron work, connections, etc., which bring it up altogether to about 65 tons; and it is obvious that to run this ponderous weight up and down the shaft without lifting any water would require a very considerable amount of power; that is to say, a very large percentage of the power must be absorbed in overcoming the friction and inertia, 50 per cent of which is evidently done away with by reducing the weight of the rod one-half, while at the same time it is also evident that it reduces the wear and tear on the pulleys and bearings 50 per cent and that pulleys half the weight suffice to do the work.

"In the pump itself provision is made to prevent chambering the cylinder, both ends of which are bell-mouthed, so that at each end of the stroke the piston ring enters slightly the enlarged ends; and to compensate for the creeping down of the main rod by the wearing of the brasses on the top end of the rod, an adjusting screw is provided so that the piston can always be kept in the same position by a little attention and the chambering entirely prevented. The arrangement which renders it impossible for sand to get into the pump renders it practicable to use metal rings for packings on the piston. Soft iron has been successfully used, but almost any kind of soft metal may be used with soft packing on the inside to press the rings close against the sides of the cylinder after they become worn a little. Lead hardened a little with tin or copper answers very well, and the old rings go to help make new ones. The iron rings last about a year and the cylinder, as far as I could judge, would run about five years before it would require boring out or just as long as a pole lasts in the under shaft.

"The arrangement for taking the weight off the stuffing-box and preventing the piston bearing hard on the bottom of the cylinder in diagonal shafts does away with a great deal of uneven wearing of the piston, cylinder and stuffing-box, as well as a great deal of friction, the piston being carried straight in the center of the cylinder. By the use of these pumps and utilizing the full effective pressure of the water power, a saving of about one-third of the power now used can be effected."

Mr. Nance advocates the use of hydraulic engines in connection with these or any other pumps, because "they give a direct acting straight pull in a line with the rod, doing away with all pulleys, shafting, cog-wheels, sweep rods and the objectionable pulling and pushing motion which tries the foundation so severely. The first outlay for the hydraulic plant would be much less than for other plants. For instance, where there is a water pressure of 300 pounds per square inch, a 20-inch cylinder would lift 90,000 pounds or work 12-inch pumps (single acting) 1500 feet deep perpendicular and require less attention than the rotary arrangement."

AMONG subjects to be discussed at the forthcoming session of the Trans-Mississippi Congress in this city, February 18, are the silver question, irrigation, arid lands, public lands, mining laws, the policy of the Secretary of the Interior, Pacific and Gulf coast harbors and the Nicaragua canal. Its object is to inform the national Congress of the views and needs of the West. It has already had a distinct influence on legislation at Washington, and at each session its influence has been increasing. It is hoped that at the next Congress the Governors and Congressmen of the twenty-two trans-Mississippi States will be present. A very large number of delegates has been appointed. The mining interests of the West will be adequately represented.

Hydraulic Mining.*

A REVIEW OF THE INDUSTRY BY DR. HENRY OEGROOT.

In Eight Parts—Part III.

Flumes and Trestles.—While, for the reasons stated, the flume should, as a rule, be avoided, conditions are sometimes such as to render recourse to the structures expedient, and that independent of topographical reasons, as for instance, where there is much rock to be excavated; where the ground is broken and porous, or water is so scarce that evaporation and absorption should be reduced to a minimum. Where a large amount of lumber is required for flume building, including supporting trestles, it may be economical for the company to manufacture this material instead of buying it, to which end a cheap sawmill should be put up at or near the head of the ditch, and, as the latter is finished and filled with water, float the lumber down to points where wanted. Almost always there is in California, at the head of these ditches, and generally for a long way farther down, timber suitable for making good lumber. A sawmill erected, lumber could be made not only for the flumes and trestles, but for all other purposes connected with the mining, the cutting of sluice boxes included.

In general terms, it may be said that as much grade should be given the flume as practicable, since the greater the fall the smaller the structure required to carry a certain amount of water. The material used in the construction of a flume must be proportioned to the size and duty required of it, much being left to be determined by the judgment of

When, as often happens in excessively cold weather, there is danger of the water flow in the flume or ditch becoming obstructed by the formation of anchor ice—that is, ice forming on the bottom—the water should at once be turned out or the ice may accumulate to such an extent as to fill the channel solidly and so remain till thawed out by the return of warm weather.

When in building a flume a curve becomes necessary, the outer side of the structure must be raised to an extent corresponding with the abruptness of the deflection. This arrangement, by throwing the accumulated water to the opposite side, tends to equalize the flow over all parts of the flume. When this occurs, the boxes or sections of the flume, usually 12 feet long, have to be shortened, the posts, sills and caps at the same time being set closer together. For the more readily effecting this curve, the side planks are on their inner face cut with a saw, the bending of the plank closing these cuts tightly.

For the construction of a box or 12-foot section of a flume $2\frac{1}{2}$ feet square, 261 feet of lumber, board measure, are required, being at the rate of 106,100 feet per mile. For a flume four feet wide, three feet deep and one mile long 241,560 feet of lumber are required, while for one of these structures seven feet wide and four feet deep of equal length 303,160 feet of lumber would be called for.

Iron Pipes.—Among the obstacles encountered in the conveyance of water to points where required for consumption or use are elevations above and again depressions below the common ditch level. For surmounting the former, recourse to iron pipes may be had if sufficient head to force

pressure, the pressure exerted having ranged from 74 to 384 pounds per square inch.

Where leakages occur in the slip joints of iron pipes, these, if but slight, can be stopped by throwing in a few bags of sawdust, or, if somewhat large, by driving in soft, well-seasoned wedges of pine which, swelling, make a very close joint. If the leak be extensive, recourse must be had to iron grip-bands, clamped on and drawn together with screws or wedges.

The Bracketed Flume.—When running a ditch-line for the Miocene company operating in Butte county, the surveyors encountered a depression at the foot of a perpendicular wall of basaltic rock, 450 feet high. To carry the water over the depression required for the support of the flume a long trestle-work, 186 feet in height. Appalled at the cost of building and maintaining a structure of this kind, the company's engineer, W. H. Bellows, conceived the plan of suspending the flume on strong iron brackets inserted into the face of the cliff, at a height of 118 feet above its base, which plan, having been approved by the company, was afterward carried out. The cut herewith shows the manner in which this flume is built and hung to the side of the precipice for a distance of 486 feet. The brackets are made from 30-pound "T" rails, bent in the shape of an "L." One of the larger arms of this "L," ten feet in length, is inserted in a hole drilled in the face of the rock, whence it extends horizontally, supporting the bed of the flume. The shorter arm, two feet long, standing at a right angle with the other, has its upper end shaped into an "eye," into which a strong iron rod is hooked, its upper end being fastened in the rock above.

These brackets are set eight feet apart and were tested to support a weight of $14\frac{1}{2}$ tons each. The flume resting upon them is four feet wide and three feet deep, having a carrying capacity of 3000 miners' inches.

The trestle shown in the plate is 86 feet high. At another point on the line of this ditch is a similar structure 1080 feet long and 80 feet high, with still another 136 feet high.

Digging Gold on the Snake River.

Many stories are told about the wealth of gold sprinkled throughout the Snake river country in Idaho. As a general thing the gold is very fine, the particles being of so light weight as to be elusive. Save when worked on a large scale it is difficult to make good wages in recovering the gold. Numerous bars along the river would prove profitable could water be commanded for sluicing or hydraulicking. An adequate supply is hard to obtain, from the slight and gradual fall of the stream and the level character of the outlying lands. To overcome this lack of water, as well as to insure sufficient dumping ground, a big floating gold-saving dredge has been constructed and is now at work on the Idaho bank of the river about ten miles above the Payette. It is a stern-wheel flatboat propelled by steam. Substantially constructed, 65 feet long and 32 feet wide, it is equipped with a 35-horse power marine engine and boiler and adapted in every way for navigating Idaho's great waterway. With a slight alteration it could be transformed into a steam dredge and used to scoop up sand and gravel from the bottom of the stream. That has never been attempted. As in the past, operations are now confined to working bars out of the channel of the river.

As described in the *Helena Independent*, the method pursued is to anchor alongside one of these gravel deposits, and, by the use of scrapers, bring the material to be handled within reach of the gold-washing machinery with which the craft is rigged. The gravel is scooped up by buckets attached to an endless chain. There are 48 of these receptacles on a belt 60 feet in length, and each has a capacity of about 20 pounds of dirt, which is delivered into a hopper. This is also an agitator, and the process employed may be described as a steam rocker, with the exception that it has an end motion instead of one sidewise. The gold is caught on copper plates with quicksilver. The tailings are carried off in sluice boxes by a stream of water of 150 inches, supplied by a China pump, run by the engine which drives all the other machinery. The gravel is worked so thoroughly that no gold escapes in the tailings that are dumped into the river. An average of 100 tons of gravel are handled, and for this work three men are employed—an engineer, one to work the scraper, and another who shovels the dirt into a pile so that the buckets can scoop up a full load. The bar now being worked covers an area of 10 to 15 acres. The gold is on top or close to the surface, and will not pay to handle at a greater depth than one foot or eighteen inches. This shows a value of $1\frac{1}{2}$ to 3 cents a pan. A clean-up is made every night, and the average of the runs for the first three days was very satisfactory to Thornton Williams, the owner of the craft. He says he expects to take out upward of \$100 a day as long as he works.

Bracket Flume, Miocene Company.

the builder. Usually posts, sills and caps, made from 3x4-inch scantling with 4x6-inch stringers, will suffice for a flume $2\frac{1}{2}$ feet square—timbers, larger or smaller, being employed in proportion to the dimensions of the flume, the posts, sills and caps being set $2\frac{1}{2}$ to 3 feet apart. For lining, well-seasoned, first-class 1 $\frac{1}{2}$ -inch boards should be used, the seams being covered with pine battens $\frac{3}{4}$ inches wide and $\frac{1}{2}$ inch thick. An open space of a few inches is usually left between the upper edge of the planking and the cap. The posts should be let into the ends of the sills and caps to the depth of an inch and a half, but not mortised or tenoned. If thought necessary to strengthen the flume, the sill may be extended a foot or two beyond the post and side braces be nailed thereto. On the cap pieces a plank is placed to facilitate foot travel along the flume.

Where the latter rests on a trestle or scaffolding, the supporting posts and sleepers of these structures should be well charred to prevent their decay. High trestles ought to be anchored with strong wires or wire rope as a protection against the force of the wind. It is well to keep always some water flowing through the flume, as the swelling of the planks incidental to the change from a moist to a dry condition tends to induce leakage and draws the nails. As with ditches, waste gates ought to be placed at suitable intervals along the flume, that it may readily be emptied should occasion require. Where exposed to snow-sildes, it is customary to make an open cut in the mountainside, and, having placed the flume in the excavation, cover it with a shed composed of heavy timbers roofed over with planks or logging.

*This article was prepared by the late Dr. De Groot for the Eleventh Report of the State Mineralogist, just issued; but its publication with that of much other valuable matter was prevented by the necessity of revision and omission, so that the volume might be reduced to reasonable limits. It covers familiar ground, but is, on the whole, a complete and careful review of the industry and hydraulic-mining methods. The article has been furnished this paper by State Mineralogist J. J. Crawford.

the water over the obstruction can be obtained without going up the ditch too far, thereby necessitating the employment of an objectionable length of pipe. So, too, the elevation may be pierced with a tunnel if here again the cost of the adit is not so great as to make its construction impracticable. There being no other alternative, resort to one or the other of these expedients must be had, if either be feasible—a point to be determined by the preliminary survey—or else the projected enterprise must be abandoned.

Where the trouble to be overcome consists of a depression of the surface so deep as to preclude recourse to fluming, then the iron pipe in the form of an inverted siphon must be employed, where the conditions make this practicable.

The most remarkable feat of this kind extant or on record was that achieved by the Spring Valley Canal Company, who, for the purpose of conveying 1500 inches of water carried by their ditch across a deep canyon in Butte county, laid down a 30-inch iron pipe extending from one side of the gorge to the other, a distance of 14,000 feet, the point where the water enters this pipe being 980 feet above the bottom of the canyon and 150 feet above the point where it makes its escape. The water here entering the pipe, therefore, had a "head" or hydraulic pressure of 150 feet, yet at this end of the pipe it never attained a height of more than 50 feet above the point of discharge, at the opposite end, a fact denoting that a much smaller pipe than that laid down by this company would have sufficed for the above service. This pipe, which under the pressure mentioned discharged 53 cubic feet of water per second, was made of ordinary English iron, and, although it has now been in use over 18 years, it is still in good condition.

In its construction No. 14 iron was used for 150 feet pressure; No. 12 for 275 feet pressure; No. 10 for 350 feet pressure; No. 7 for 475 feet pressure; $\frac{1}{2}$ iron for 600 feet pressure; 5-16 for 850 feet pressure, and $\frac{3}{4}$ for 900 feet

The Red Point Drift Gravel Mine.

Abstract from Paper Read Before Technical Society of the Pacific Coast by Chas. F. Hoffman, M. E. Printed by Permission of the Society.

Before the Technical Society of the Pacific Coast, Friday, January 5, 1894, a valuable paper on the "Red Point Drift Gravel Mine," by Charles F. Hoffman, M. E., was read by Ross E. Browne, M. E. The mine was opened and worked under the direction of Mr. Hoffman, and he therefore had exceptional facilities for securing accurate and desirable information as to the cost and method of development. These he presented in very complete form to the society. The Red Point is a fine example of the systematic and economically worked drift mine, and a synopsis of Mr. Hoffman's paper, which follows, will be instructive to all interested in this branch of mining.

The Red Point is a drift mine in one of the ancient lava-capped channels of the Forest Hill divide, Placer county California. The elevation is about 3875 above sea level. It belongs to the Golden River Mining Company, of Paris. The channel is blue gravel and consists of boulders principally of metamorphic chists and porphyries, with a small percentage of quartz, intermixed with small pebbles and sand, and occasionally fine particles of iron pyrites. The gravel is "free," and is washed without crushing. Blasting, however, is required to facilitate extraction. The depth of gravel is from a few inches to 16 feet—generally seven or eight feet at the center of the channel. It is immediately capped with volcanic cement, which forms a good roof to work to. The overlying cement has a depth of 500 to 1000 feet. The washed and rounded boulders are often two or three feet, and occasionally six or eight feet, in diameter. The gravel often has a glistening appearance and is found to be coated with infinite quartz crystals. Here the gravel is barren. The gold is mostly in the form of "scale gold." In places there are streaks of coarser gold, and occasional nuggets of one or two ounces in weight.

The yield of gold may be divided into the following percentages: Coarse, 15.68; medium, 48; fine, 36; powder, 0.32. The gold varies in fineness from .928 to .937, valued at \$18.90 net per ounce. Most of the gold is found near bedrock. In some sections, however, it is mainly in the gravel above. The richest spot in the mine was found in a layer of gravel from 6 to 12 inches above bedrock. At this point the bedrock was hard and smooth and the channel straight. Some of the gravel was scraped up by hand, and contained as much as 33 ounces to the pan. For two months the average yield was \$7.50 per carload of 22 cubic feet. There is one rule which applies to this channel and perhaps to others with beds of stratified rocks. The consecutive strata having different degrees of hardness will form riffles, so to speak, along or across the channel according to its course. When the gold-dust strikes these riffles it is washed along them in the direction deflecting least from the course of the stream, and concentrates toward the rim. If it strikes at right angles, it lodges in the center or scatters to right and left. This rule holds good for the main bodies of pay gravel. Of course, if the bedrock is once covered, it no longer governs the travel of the gold in this way, and this rule applies only to the pay streaks on the bedrock. In these main bodies the quantity of gold varies much locally. It is generally more abundant in cracks, formed by the cleavage of the rock, at right angles with the strike; also around quartz veins, which are rough on the surface and hold the gold more readily, or where the slate is soft and thinly foliated. The lowest rut in the channel contains very little gold—sometimes some coarse gold—but the bulk is thrown on the sides or higher rock. It is also more plentiful on the down-stream side of islands and very large rocks.

The tunnel was driven through slate bedrock in the blue channel, being tapped by means of an upraise 1840 feet in the tunnel. It is 7x8 in the clear, has a grade three inches in 100 feet, and when originally run, had a double track for the first 100 feet, with a drain ditch in the center, and, from there on, a single track, with drain ditch in one side and switches every 500 feet. The switches and double track have since been removed. The rails are 16-pound steel, with gauge of track of 20 inches. The air compressor, located 200 feet vertically above and about 300 feet from the mouth of the tunnel, conveys air through a three-inch pipe. A wagon road, 6500 feet in length, was necessary to be built to the compressor site; also, it was necessary to bring water 2800 feet in a two-inch pipe to supply the works.

Work on the tunnel proper was begun July 2, 1886; six men ran 108 feet by hand; the compressor was started August 5th, and had reached a length of 1552 feet by January 31, 1887. The last 1444 feet were run with an average of 20½ men per day. Delays and accidents made the time of work on the 1552 feet exactly 6½ months, or an average of 234.1 feet per month, including hand work. For two

consecutive weeks the largest runs were 71 and 84 feet, respectively (six days each), or 11.82 and 12 feet per day, respectively. The tunnel runs diagonally across the strike of the rocks, which consist of strata of metamorphic slate, alternating with sheets of diabase diorite and barren white quartz. The regular force consisted of 15 miners (8 hours), 2 engineers, 2 drivers (12 hours), 2 blacksmiths, and 1 timberman (10 hours). The two latter worked only in the daytime. The cost of surface improvements was as follows:

Road.....	\$ 963.00
Yards, dump and trails.....	508.05
Boarding-house, office and other buildings.....	2,310.10
Water works.....	604.94
Air compressor, tank, pump, drills, etc.....	7,819.86
Air compressor (labor).....	970.00
Eight iron cars.....	1,200.00
Two tunnel horses, team horses, etc.....	705.00

Total cost of plant.....\$15,080.95

ACTUAL COST OF TUNNEL.

	Total Cost.	Per Running Foot.
Labor.....	\$11,418.47	\$7.36
Powder.....	2,641.47	1.70
Fuse.....	263.07	.17
Wood.....	1,105.50	.71
Charcoal.....	320.80	.21
Candles.....	290.40	.19
Footplank and Ties.....	147.10	.09
Timbers.....	46.76	.03
Steel Rails.....	510.00	.33
Horse Feed.....	281.25	.18
Materials, steel, oil, etc.....	693.00	.45
Freights.....	1,000.00	.64
Totals.....	\$19,239.85	\$12.40

With present reduced prices for powder, etc., such tunnel would now be run for \$11.25 or less per running foot.

From the upraise in the tunnel (at 1840 feet) the channel was worked both up and down stream. A branch tunnel was run up stream for 1300 feet, and two upraises made to the gravel. The second upraise is 3040 feet from the mouth. At this point a slope was raised into the channel with a grade one foot in two and one-half, and work on the extension of lower tunnel abandoned.

The system of workings is by a main gangway in the lowest part of the channel, with diagonal crosscuts every 100 feet. No logging is needed in timbering. Only posts and caps are required. Natural pillars of gravel are occasionally left. About one-third of the gravel, being of boulders over five feet, is not removed.

Two Baker blowers (4 and 4½) are used for ventilation. One is run by steam, the other (just installed) by water for one-half the year.

Four horses are needed for transportation of the gravel. The cars have 22 cubic feet capacity. The gangway trams are six cars; the tunnel trams are ten cars. There is a self-dumping charr at the dump. The total distance from the breasts to the dump is 6514 feet, or nearly one and one-quarter miles, 3273 feet being in the gangway and 3241 feet along the tunnel. The number of cars raised is 30.

The average number of men employed daily is 58.5 (22 white, 38.5 Chinese); average cost of labor per man, \$2.23; average number of carloads extracted per day's labor, 1.87. This estimate includes all hands. A man breasting gravel will average 2.80 to 3 carloads a day, sometimes more; the maximum by the whole force is 220 carloads.

The pay roll for six months, omitting labor for ventilation and transportation, shows an average of \$3169.75 per month. This gives for 3064 carloads a labor expense of \$1.03 per carload.

The cost of materials used for one month is, on an average:

1101 pounds powder, No. 2, at 10 cents.....	\$110.10
4800 feet fuse at \$5 per M.....	24.00
1766 caps at \$5 per M.....	8.83
615 pounds candles at 10½ cents.....	64.57
11 gallons coal oil at 26 cents.....	2.86
5 gallons engine oil at 65 cents.....	3.25
1½ gallons cylinder oil at 90 cents.....	1.35
6 gallons lard oil at 90 cents.....	5.40
11 gallons car oil at 35 cents.....	3.85
131 bushels charcoal at 20 cents.....	26.20
3662 pounds hay at \$25 per ton.....	45.77
1669 pounds barley at \$1.80 per cental.....	30.04
33 cords wood at \$2.87.....	94.71
Timbers, lumber, hardware, air pipe, rails, car wheels and sundries.....	236.00

Total average one month.....\$670.73

Total expense per carload is:

Ventilation.....	\$0.11
Transportation.....	.16
Labor.....	1.03
Materials.....	14½
Management.....	19½

Total per carload.....\$1.64

Total production during five years from January 1, 1888, to December 31, 1892, was 140,345 carloads averaging \$308,245.40, or \$2.20 per carload. The total production of the mine has been \$363,473.60 from 5073 running feet of channel, or \$71.65 per running foot.

The following percentages of the total yield are obtained from the different sluices (average of 12 months):

	Percentage.
Upper sluice (without quicksilver).....	82.48
Lower sluice (with quicksilver).....	3.89
Canon sluice (36 feet quicksilver).....	2.86
Canon sluice (182 feet quicksilver).....	3.24
Tailings.....	5.72
Panning tub.....	1.63
Blowings (back sand).....	.18
Total.....	100.00

Concerning Coal Mining Machinery.

In statistics recently issued by the Illinois Bureau of Labor there are some figures that are specially important just now. The *Engineer* has been reviewing these, and says that in some of the coal seams in that State the use of machines has been found profitable, and the number of the mines in which these machines are at work is increasing. Last year, according to the official statement, there were 41 mines in which machines were at work—the number of the machines thus employed being 300, and the amount of the men employed in connection therewith being 3646, or over 10 per cent of the total for the State. The machine mostly used is the Harrison machine, but the Ingersoll, the Yock, and others are employed, and all are operated by compressed air, except the Sperry machine, of which three are used, with the electric current. On the average 12 men are employed to each machine, and the product in the mines where machines have been used exclusively is about 13,758 tons for each machine in a year of about 229 days of active operations. The wages of the men vary considerably. Those who operate the machines average from \$2.25 to \$2.50 per day. The blasters receive from \$2 to \$2.25 per day; the timbermen about \$2; the helpers and loaders from \$1.75 to \$2 per day; and the laborers from \$1.50 to \$1.75 per day. Some facts are also given relative to the yield in the mines of coal for the powder used in blasting. In the machine-worked mines the average was 97 tons for each keg of powder; but the average in the hand-wrought mines is put as about 39 tons per keg only. The qualification is, however, necessary, that it is mainly in the mines where the seams of coal are thick that the machines are successfully used, and hence the powder necessarily dislodges a larger amount of coal per given quantity than it does in the thinner seams where hand-working is general.

In two of the five mining districts of the State of Illinois, the inspectors of mines report that electric coal-cutting machines are being put down or experimented with; and as the production in mines where machines are used is slightly increased in its proportion to that of the whole of the mines, it must be expected that there will be in the future a larger yield of coal by the machines. Thus, the area of the use of both hand and machine work is being defined by experience; and in the same way it is to be expected that the relative value of the different kinds of machines will in time be fully determined. These figures have an interest and value that is very great at the present time when the question of the cost and methods of extracting coal has become one that is most important in its hearings in all the coal fields, and in its effect on other industries. The use of electrical coal cutters as well as other kinds of motors for the purpose is being now tried in some mines on a scale that is at least important in furnishing the experience that is essential to enable a decision to be formed as to their relative economy in our mines, and thus it is probable that as labor is made more costly there will be a fuller employment of machinery.

Tin Mining on the Malay Peninsula.

The Kong Loon Kongsu mine, on the Malay peninsula, may be taken as typical of that district, says the *Manufacturers' Gazette*. An examination of the mine itself reveals the proportions of productive and waste matter to be: Strippings, 3.5 meters; pay gravel, 2.8 meters, or, in other words, a respective percentage of 55.6 and 44.4. Forty-one cubic meters are required of pay gravel for one ton of black tin ore, which means that 92.48 cubic meters must be mined per ton of ore, of which about 66 per cent is the white metal. The cost per cubic meter of gravel, Mexican money, is \$1.18. Sixteen kilograms of gravel (the weight of a basketful) raised 6.3 inches with a velocity of 5 centimeters per second, is regarded as the average work accomplished throughout a day of 6.5 hours, or actually 18,720 kilogrammeters per day. At Kotta Ranah the average workman seems to raise but 11.6 kilograms (25.59 pounds) a distance of 1.72 meters with an average velocity of 3 centimeters per second, or 9605 kilogrammeters per day of 7.66 hours. Perak is cited as more proficient in value of workmen, but even here the work done only equals about one-third that accomplished by white labor in temperate climates. The Eastern mines are usually worked by Chinese, either imported direct by the operating company or obtained through one of the various agencies established for that purpose.

The tools of the Chinese miner are primitive, consisting of a crowbar for breaking the harder rock, a chankol, or hoe, for handling the looser material, and with which it is put into the rattan basket in which it is carried out of the mine. A notched stick is used for a ladder. In shallow mines the baskets of ore are carried out on the back, but the old-fashioned well-sweep is brought into play in the deeper pits; also for handling the water. In the Malay peninsula steam pumps have been introduced.

The Prospects of Gold.

Mr. T. A. Rickard of Denver, contributes to the *Engineering Magazine* an interesting article on the prospects of gold production.

The highest yield on record for the whole world was in 1853, when it had a value of \$155,000,000. In 1890 only \$120,000,000 was reported. Since then there has been a fresh increase, but the output for 1892 was quoted by the director of the United States Mint as only \$130,816,227. To this might perhaps be added from \$5,000,000 to \$7,000,000 for China, whose production is omitted from the figures for the last two or three years. The distribution of the principal yield last year was as follows: Australasia, \$33,870,800; United States, \$33,000,000; Russia, \$25,801,645; South Africa, \$22,069,578; other countries, \$18,330,249. In the United States, in 1892, the leading contributors to the stock were the following States: California, \$12,000,000; Colorado, \$5,300,000; South Dakota, \$3,700,000; Montana, \$2,891,386; and Idaho, \$1,721,364.

Inasmuch as the United States, the colony of Victoria, Russia and South Africa, are now the principal producers, the outlook in those countries is next discussed by Mr. Rickard. In California he attributes the decline from \$81,294,700 in 1851 to only \$12,000,000 last year to legislation forbidding hydraulic mining and to the exhaustion of the auriferous deposits in the alluvium. No recognition is given in the article to question to recent attempts to resume placer mining in old river beds and the partial removal of restrictions on hydraulic mining; but these, if the gravel is already pretty well cleaned out, leave little encouragement.

Mr. Rickard thinks that quartz mining, which does not yield so handsomely as the earlier methods did for a time, is now our only resource. Indeed, he deprecates the romantic ideas derived from Bret Harte's stories, and insists that the miner of to-day wins success, or in any other industry, only by energy, judgment, science and common sense. "Gold is rarely got by digging at grass-roots," he says. So, too, in Victoria, the falling off from \$63,000,000 in 1853 to \$13,481,793 was explained by an official commission, after an investigation, to the thoroughness with which the alluvium had been worked, and to the difficulties and expense of vein mining. Although the largest amount of gold credited to Russia was secured several years ago (in 1880, \$28,759,860), Mr. Rickard regards the industry there still in its early stages. It deals mainly with the gravel at present. But too much obscurity involves the subject to make it safe to prophesy concerning that quarter of the globe. In the Transvaal there has been a rapid development in gold production from 1887, when the output amounted to \$755,212, to 1892, when it was valued at \$21,190,085; but the so-called "reefs" from which the precious metal is obtained are more like quartz lodes than alluvium, in Mr. Rickard's opinion; and he evinces scepticism regarding the alleged uniform richness and inexhaustibility of these deposits, reminding the reader that no California pioneer of 1849 expected the treasure so profusely strewn about him to give out, any more than the sanguine South African miners now look for a similar experience.

The existence of gold in considerable quantities in other lands where it has not been touched is granted by the writer here quoted, but he says that in most of those cases its location is amid unfavorable conditions. "To predict a near exhaustion of the gold deposits of the globe," he remarks in conclusion, "would be foolish; but it is certainly true that the difficulty of getting gold is daily increasing."

The last statement is of course to be taken in its broad sense as applied to the world generally. The difficulties increase as the surface deposits are exhausted, and gravel beds give out; but in California the change of conditions is gradually for the better. The industry was at its lowest ebb when hydraulic mining was stopped; but, as geological and mineralogical knowledge has increased, and mining methods and machinery been improved, confidence has returned, and the obstacles are not what they once were.

Cyanide in South Australia.

The *Glasgow Herald*, Thursday, Dec. 7, 1893, has the following: The government of South Australia recently appointed the Inspector of Mines (J. V. Parkes) to proceed to what is described as the Hills district (Blumberg and Mount Pleasant) and ascertain if the district offered sufficient inducement for it to erect a battery for the treatment of refractory ores by the MacArthur-Forrest cyanide process. Mr. Parkes met with 150 land-owners, miners and others and explained the position of matters. He said he had been drawn towards that place because of his knowledge of the many reefs which he considered payable, and which he knew were rich, and because of the stone that he had tested. It was a pity that the gold should remain in the earth when they knew that there were means of extracting it. The chlorination process was very good with respect to certain ores. Having proved that chemical re-

duction by chlorination or cyanide of potassium would yield high results, he had given up the idea that refractory ores could be treated profitably by amalgamation. On his return from the northern territory he called in at Ravenswood, where observed the MacArthur-Forrest cyanide of potassium treatment, which was very simple. The ore was put into the vats with the cyanide solution. He saw them agitating the ore for about four hours, and the result was that 93 per cent of the gold was taken out with no more trouble in cleaning up than with an ordinary battery. Parliament had resolved to erect a plant on a suitable site being fixed upon.

The *Register* (of Adelaide) had the following on Nov. 1: Ministers' eyes glistened on Monday morning—or at any rate it may fairly be inferred that they did—for beside the dusty, musty dockets they were enabled to gaze on glittering gold. It consisted of 54½ ounces obtained by the cyanide process at the Virginia mine, the first cake of the precious metal obtained at Wadnamanga by chemical reduction, which, it is hoped, will make a new and prosperous era in gold mining here.

The Arizona Big Bug District.

Prescott, Ariz., Cor. of *Denver Mining Record*.

A great many Colorado people are coming to Arizona just at the present time. Some are old-time prospectors, some are mine owners looking for new localities in which to invest, while others come because of the milder climate during the winter months. It is unfortunate for this great mineral section of the world that the laws of this territory are not more specific, or, in other words, a little more binding. A few men have taken possession of hundreds of claims, and after once locating all they have to do is, on January 1 of each year, to relocate by simply changing stakes and recording relocation; and so a Colorado prospector, used to locating, surveying, recording, and doing a \$100 worth of assessment work, runs up against unpleasant obstacles in coming here to prospect. Such is the situation, but it will be remedied in time. An attempt was made at the last session of the Territorial Legislature to adopt a greater portion of the Colorado mining laws; but the opposition was too great. The mine investor also, in coming here, finds in this a stumbling block.

In the Big Bug mining district are two kinds of deposits. One is that of iron, and the other of onyx. Of the former there is a vein 17 feet in width which averages 70 per cent hematite iron liberally charged with lime. In four tests made there showed less than 10 per cent silica and over 20 per cent lime. The mine has been extensively prospected along the surface and has a shaft 100 feet in depth. It is owned by Joe Mayer, of Big Bug, who has contracted with the copper smelter, just below the property, to furnish a given quantity daily, he receiving \$3 per ton for it on the dump. He considers the net profit of it to be \$2 per ton.

Of the onyx deposits much might be written, for there are acres of it not 100 yards from the Black Canyon stage road where it passes Mayer's station. While the quantity of it is great, the quality, so far as the quarry has been opened, gives evidence of being first class. Dr. F. Wm. Ihne, of Chicago, well known in Colorado as examiner of properties, has made a critical expert examination of the beds at this point, and he pronounces them the greatest ever yet discovered.

So far there has been located about 400 acres, one body of about 220 acres being owned by Joe Mayer and others, of Prescott, who have bonded the same to New York parties for the sum of \$200,000. A number of payments have been made, and it is only a question of time when this company will have erected at this point works for the purpose of reducing the blocks to proper size for shipment. Mayer's station, where the quarries are, is 78 miles from Phoenix and 28 from Prescott.

There is another bed of black and white onyx situated about 12 miles east of south of those at Big Bug, which are owned by Sheriff J. R. Lowery and Charles Bishop of Prescott. So far as opened up the stone appears good and is pronounced by experts to be a very fine onyx. The owners have the same bonded to St Louis and San Francisco parties.

Six miles south of Camp Verde, on the Rio Verde river, and 35 miles due east from Prescott, is a large quarry of lithographic stone. The same was located a year ago last July, but has never been extensively opened, though prospected so as to show a 50-foot face, and back into the mountain about 15 feet. West of that opening are two others of something like a six-foot face 100 feet in length. Until lately it has been believed that these deposits of carbonate of lime carried too much iron to admit of its use for lithographic purposes; but all this has been dispelled by tests made in Los Angeles, Chicago, Cincinnati and Washington. Prof. Blandy, ex-territorial geologist, has lately made a thorough examination of this quarry and says he found two beds of three to four feet in thickness, and is of

the opinion that as depth is gained the quality will improve. The stone appears to be uniform in grain and texture. Several openings have been made showing from a 60 to 100-foot face, and no difference in quality appears to exist in either stratum. In the gulch 350 feet below flows a fine stream of water the year round, and of sufficient fall to give power to any size mill which may be erected to work upon this stone. This quarry is owned by George W. Line and others of Prescott, who expect to dispose of it to Los Angeles and New York parties.

Buying Mining Machinery.

A great many mistakes are made in the purchase of mining machinery, and the chief cause of these errors lies in the fact that the purchasing parties are too eager to get the machinery on the ground before they have demonstrated what they can count on for an output, or by the purchase of machinery which is not required on the property and will not do the work required of it, says the *Spokane Mining Review*. As a rule the fault lies with the purchaser.

The first thing to know is what the mine contains. Tests of the ore should be carefully made at various stages of the property's development, all of which should be carefully noted and recorded in a book for that purpose. Not only should the value of the ore and the different mineral contents be learned, but in every instance the owner should know in what form the mineral occurs. After this has been done and a sufficient amount of ore is taken out and exposed to justify the purchase of a mill or concentrator, unless the owner is well informed himself or has a practical man of experience with him, he could do no better than to go to a responsible mining machinery dealer and lay all the facts before him, when, in the majority of cases, he would get the proper machinery and be able to successfully operate his mine.

There are very few mining men who are competent millmen, for like dentistry which is practiced to a greater or less extent by physicians, and particularly where dentists are not available, there are few who are good dentists. Milling, concentrating, smelting and refining are each adjuncts of mining, and yet few miners are masters of even one of these adjuncts any more than a millman who has spent many years in that business is a first-class mining operator. But the salesman of mining machinery has a varied experience in his business. He is called upon to put mills and concentrators into all kinds of mines, and the safest way to do, unless you are yourself a practical millman, is to enlist his attention and avail yourself of his experience. In that manner you may turn a worthless enterprise into a profitable investment. But the first rule is to know that you need machinery and the property will justify or demands its erection.

Big Hydraulic Mining Enterprise.

Abridged from the *Plumas National Bulletin*.

James O'Brien, the mining man, will be up from San Francisco some time next week, and upon his arrival the Quincy Mining & Water Co. will begin constructing the stone dam across Spanish creek at the Devil's Elbow, and will vigorously prosecute the work till this important task is finished. A few days ago the men employed on the big ditch and other work were paid off. The permit to build the dam at the Elbow, at the time it was granted by the Debris Commission, was considered the most important action taken by that body. The dam site is one of the best that could be found—in a deep, narrow canyon, where, by making a cut across an elbow, the water can be discharged off at one side of it, over a solid rock bottom, thus rendering the dam perfectly secure when finished. Behind this structure will be an immense impounding reservoir, rendering it possible for the company, with smaller and less expensive dams to be built, to operate for years on the large beds of rich gravel which it owns.

The water privilege owned by this company is one of the largest and best in this part of the State. The ditch, whose capacity is 2000 miners' inches, is the outlet of a large reservoir near Spanish Peak, and which husbands the waters of the deep snows which meet there late in the spring. By raising the dam of the reservoir the water reserve has been largely increased, enabling the company to mine fully seven months annually. The corporation now owns 2200 acres of gravel, covered by its water system. This system virtually controls all the mines along the line of its ditches. The ground worked there in the palmy days of hydraulic mining yielded large returns. Indeed, the shipment of gold from Spanish Ranch has run up into millions. There is no reason to doubt that the remaining large gravel deposits to be mined by the Quincy Mining & Water Co. will yield large returns upon the investment. The past record of that section as a gold producer is convincing proof of this.

Colorado's Mineral Output.

Colorado's output of gold, silver, lead and copper for 1893 amounted to \$30,218,837.

Taking into consideration the low price that has obtained throughout the year for three of the metals, the total is remarkable, and it shows that, despite the hostile legislation against silver and the general depression which has affected the price of baser metals, the State continues to uphold the pre-eminent position which it gained years ago.

Had not the price of silver fallen to an unprecedented extent, the output of 1893 would have been very much greater, but as matters stand there is no ground for complaint.

There were 23,017,089 ounces of silver produced from Colorado ores during 1893, as compared with 26,542,135 ounces the previous year. The first half of the year the output was ahead of any other year, but when silver fell so rapidly about midsummer the industry was paralyzed for a short time.

The stimulus given to gold mining by the discovery of new camps of great richness and by the fall in silver is very apparent in the output for 1893, which exceeds last year's by nearly \$2,500,000.

The following table from the Denver Republican will show the product of the smelters, etc., for the year. As some of the works do not divide the Colorado ore from that treated from outside the State in their reports, the amount has to be approximated:

PRODUCTION FROM COLORADO ORES IN 1893.								
Source of Production.	Copper. Pounds.	Lead. Pounds.	Silver. Ounces.	Gold. Ounces.	Copper. Value.	Lead. Value.	Silver. Value.	Gold. Value.

San Juan smelter, Durango.....	200,000	5,779,503	1,081,560	16,190	20,000	209,217	823,236	334,647
Standard smelter, Durango.....	2,528,858	367,697	21,718	252,235	285,725	448,911
Brace smelter, Rico.....	25,000	222,000	44,337	168	805	35,050	3,410
American zinc-lead works, Canyon City.....	300,000	940,000	95,000	370	30,000	34,028	74,100	7,647
Holden smelter, Aspen.....	224,219	78	173,110	1,612
Eastern smelters.....	200,000	53,740	1,112	7,240	41,917	22,985
Retorts and bullion shipped direct.....	17,000	350,000
Totals.....	8,007,741	89,333,213	23,017,089	375,771	307,271	3,811,223	17,797,890	7,802,453

The marked superiority of the Colorado smelting works for the treatment of all kinds of ore is being manifested in the increasing amount of ores received from other States. During the last year the increase has been unusually large.

The Raber Amalgamator.

The official description in letters patent granted by New South Wales to Nathan Leroy Raber of Benton county, Oregon, for his improved amalgamator is as follows:

The invention seeks, among other improvements, to provide simple means whereby the sand, pulp, etc., are properly directed to the mercury; also means for keeping the mercury constantly sensitive, pure and active; and devices by which the adjustment of the main frame or box and the mercury cup may be independently effected, so that either the main frame or the mercury cups may be adjusted to different angles to the horizontal without necessitating a corresponding change in the other part. The inventor employs a main frame, which is in the nature of a shallow box having vertical sides and stepped bottom, such bottom consisting of a series of steps formed with what may be termed the risers and treads. These risers and treads and the sides are properly joined, usually by rabbetting, and are firmly nailed and clamped together. At its upper end the main frame or box is closed by a cross-board, while its lower end is open, so that the tailings, pulp, etc., may freely discharge. The sides are braced by the beams or bars extended between their upper edges and firmly se-

cured to both sides. These tie bars not only brace the sides of the main frame, but they also serve as supports for the holders of the mercury renewing materials. At its four corners the main frame is provided with adjusting screws or bolts turned through threaded bearings and against base supports or seats, which may be on sills. By this means the frame or box may be adjusted to any desired inclination, both longitudinally and laterally, and so be set to suit the quality or quantity of the material being treated. Upon each step is placed a plate of silver-plated copper, held at its upper edge and sides by cleats, and projecting at its lower edge beyond its supporting step, so that each plate overlaps at its lower edge the upper of the plate on the next lower step. Beneath the lower projecting edge of the plates are arranged the mercury cups or troughs, which rest upon the steps, or may be otherwise supported as desired. These cups are supported, so that they may be adjusted independently of the adjustments of the main frame, such independence of adjustment co-acting in permitting the angle of the main frame to be varied to regulate the speed with which the material may pass through the apparatus, and at the same time enabling the angle of the mercury cup to be retained or varied as may be desired. The troughs are carried upon suitable brackets or supports at each end, which are provided with adjusting screws bearing upon iron plates or carriers rested upon the steps, and these screws permit the adjustment of the cups.

An enterprise for the working of the Murray, Idaho, placer district on a large scale is being talked of, with reasonable prospects that it will go through this winter, says the Spokane Review. Syd Mills, who owns nearly 100 placer locations in the vicinity of Eagle creek, and who also controls several lakes in western Montana, in the Bitter Root mountains, from which it is designed to convey water 20 miles to the diggings, is one of the principal parties to the proposed scheme. John M. Burke, who is now in the East, has a bond on a large amount of old wash on Pritchard creek. The promoters see the possibility of uniting for the purpose of securing a large quantity of water. It will cost from \$100,000 to \$300,000 to develop the plan, which has been pronounced feasible by mining engineers.

ALL of the larger gold mining properties about Baker City have ceased operations for the winter because of the depth of snow on the mountains. A large number of men have in this way been thrown out of employment, but they are of a class that are fully prepared to take care of themselves and their families during the winter months.

MINING, IRON AND WOODWORKING

MACHINERY AND SUPPLIES

INGERSOLL-SERGEANT PISTON INLET AIR COMPRESSORS AND ROCK DRILLS

ENGINES AND BOILERS

PARKE & LACY COMPANY

21 AND 23 FREMONT STREET, SAN FRANCISCO, CAL.

NOTICE TO GOLD MINERS!
SILVER-PLATED AMALGAMATED PLATES
For SAVING GOLD!
IN QUARTZ, GRAVEL, OR PLACER MINES. MADE OF BEST SOFT LAKE SUPERIOR COPPER
AT REDUCED PRICES.

Our plates are guaranteed, and by actual experience are proved, the best in weight of Silver and durability. Old Mining Plates Replated, Bought, or Gold Separated. THOUSANDS OF ORDERS FILLED.

Scientific Progress.

The Harvest Moon.

The time of moonrise on any day is on the average about 51 minutes later than it was on the preceding day. This retardation is, however, by no means constant in amount, being at times very much less than the average and at times very much greater. A very marked diminution in the time of retardation occurs about the time of the full moon which falls in September, says the *Popular Science News*.

This moon is called the harvest moon. The same phenomenon in a less degree occurs at the time of the following full moon, which is known as the hunter's moon. The time of retardation during the harvest moon is less than half an hour in our latitudes, instead of its average value of nearly an hour, and for several successive nights the moon seems to rise at nearly the same time.

Briefly stated, the cause of the phenomena is this: At the time of the rising of the harvest moon the apparent path of the moon among the stars is much less inclined to the horizon than it is at other times, and the ordinary day's motion of the moon along this path makes an unusually small change of position of the moon with reference to its distance from the horizon.

A more detailed explanation may make the matter a little more easily understood. In addition to the ordinary apparent daily motion which the moon has in common with all other heavenly bodies, it has another motion by which it completes the circuit of the heavens relatively to the sun once a month, and the direction of this motion is generally not parallel with the direction of the diurnal motion, it being generally northward or southward as well as eastward.

Any one may see this motion by an hour's watching of the relative positions of the moon and a star near it. The diurnal motion is always on a line at right angles to a line drawn from the body of the celestial pole, the point in the heavens approximately indicated by the pole star. It is always perfectly uniform about the pole as a center, and it is this which we take as our ordinary measurement of time.

Now, consider the position of the moon and the sun at the time of full moon. The moon rises just as the sun sets. On the next evening the moon will still be below the horizon, because it has moved westward among the stars relatively to the sun, and it will not rise until the diurnal motion of the heavens brings it above the horizon. If the moon's motion were uniform and always along the line of ordinary diurnal motion, this retardation of the time of rising would always be the same, and would, as stated at the outset, be 51 minutes per day.

But at the time of harvest moon the direction of motion of the moon among the stars is considerably northward as well as eastward, and at the time of moonrise this line makes a comparatively small angle with the horizon, very much less than it does at other times of full moon during the year. Therefore, at sunset on the day after the full, the moon having moved along a line which is inclined to the horizon at a much smaller angle than usual, its distance below the horizon will be less than the average, and hence a smaller amount of diurnal motion will bring it into view—that is, the retardation of time of rising is less than it is at other times. This condition continues for several days.

Several other things, notably the inclination of the moon's orbit to that of the earth, and the varying rate of motion in the orbit due to variation of distance from the earth, tend to change the amount of daily retardation, but they do not depend upon the time of the year, and they sometimes intensify and sometimes diminish the peculiar phe-

nomena of the harvest moon. Latitude has a strong effect, and in Northern Europe the phenomenon is a much more noticeable one than it is the United States. In fact, if one goes far enough north, the harvest moon may rise even earlier on any night than it did on the night preceding.

Determination of Manganese in Manganese Bronze.

Mr. Jesse Jones, of the Chemical Laboratory of the well-known ship-building firm of Messrs. Cramp, in Philadelphia, has recently explained to the American Chemical Society the method in use in that laboratory for the determination of manganese in manganese bronze. It is an adaptation of a well-known method in common use for the determination of manganese in iron and steel. A determination can be made in less than one hour, and, as the amount of manganese in the ordinary run of work seldom exceeds 0.10 per cent, the method gives fairly satisfactory results. The following is the method: Dissolve 5 to 10 grammes of drilling in nitric acid of 1.20 sp. gr., using a large beaker to avoid frothing over. An excess of acid must be avoided, as it interferes with the precipitation of the copper by hydrogen sulphide. When solution is complete, transfer to a 500 cc. cylinder without filtering out the precipitated stannic oxide. Make up to 300 cc., and pass a rapid current of hydrogen sulphide from a Kipp's apparatus until the supernatant liquid is colorless. Decant off through a dry filter, 180 cc. corresponding to 3 or 6 grammes of sample, and boil down rapidly to about 10 cc. Transfer to a small beaker and add 25 cc. of strong nitric acid. Boil down one-half, make up with strong nitric acid, boil, and add one spoonful of potassium chlorate. Boil ten minutes and add another spoonful of potassium chlorate. Boil till free from chlorine, cool in water, and filter on asbestos, using filter pump. Wash with strong nitric acid through which a stream of air has been passed. When free from iron, wash with cold water until no acid remains. Place the felt and precipitate in the same beaker, and dissolve in ferrous sulphate, using 5 cc. at a time. Titrate back with permanganate until a pink color remains. Deduct the number of cc. used in titrating back from the number of equivalents of ferrous sulphate used, and the remainder shows the manganese in the amount of sample taken. Permanganate solution.—Dissolve 1.149 gramme potassium permanganate in 1000 cc. water; one cc. equals 0.001149 gm. manganese. Check by dissolving 0.1425 gramme ferrous-ammonium sulphate in a little water and acidulating with hydrochloric acid. This should precipitate 10 mgms. of manganese. If not, apply the factor of correction. Ferrous sulphate solution.—A solution of ferrous sulphate in 2 per cent sulphuric acid, so dilute that 5 cc. corresponds to 10 cc. permanganate solution. This is best made by trial and dilution.

Dust Over Buried Cities.

The rapid shifting by the winds of beds of sand, often destroying or menacing human works, is a phenomenon well known in different parts of the world. But the slow accumulation of the finer particles—the atmospheric dust—has attracted attention only in recent years. Most ruins of ancient cities are buried, and it has now been learned that the covering is not only the debris of decayed buildings and other works, but that much of it is atmospheric dust. The layer that becomes visible to-day on a polished surface, if undisturbed, may grow into a deep stratum in the course of centuries.

Gaseous Theory of the Earth.

The idea of M. Rateau, as expressed to the French Academy of Sciences, is that the phenomena of the earth's crust are well explained by considering that the planet's in-

terior is molten, and that a layer of gaseous matter separates it from the portion of the crust forming the continents, where the seabeds rest directly upon the igneous globe. The continental masses tend generally to rise, being forced up by the accumulating gases, while the seabeds sink. The gradual escape of the gases, imprisoned under high pressure, will in time exceed the production of new supplies, when the pressure will diminish and the continents fall in, giving rise to more or less crateriform configurations. This is the state in which the moon now appears. Assuming the crust to be 18½ miles thick, the pressure of the gases should be 650 atmospheres, their temperature 900° C., and their density nearly equal to that of water. This theory makes it clear why volcanoes in the interior of continents give off gas instead of lava, and why lines of coast volcanoes have successively receded inland where the sea has encroached.

FOR SALE CHEAP.

TEN 18" diam. suction and discharge

CENTRIFUGAL PUMPS, WITH ENGINE ATTACHED.

—Together with—

NINE UPRIGHT BOILERS, 65" diam.

—Also—

TEN FOOT VALVES, and about 300 feet of 18" diam. STEEL FLANGED PIPE to 4, 8 and 12 foot lengths.

This machinery is practically new, and was built specially for use as a wrecking plant. The pumps have each a maximum capacity to deliver 60 tons of water per minute. The plant will be sold very low as a whole or separately.

These pumps are suitable for irrigating purposes or under any conditions where a large volume of water is required to be moved quickly and cheaply.

For price and other particulars, address

To MINE OWNERS and others having Refractory Gold and Silver Ores hitherto untreatable at a profit, the MacARTHUR-FORREST CYANIDE (Patent) Process of Gold and Silver Extraction offers a solution of the difficulty.

The chief features of this process are

Simplicity, Economy in Working and Small Cost of Plant.

OFFICE:

McPHEE Building, DENVER, COLORADO

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, \$3.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

BY J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Mechanical Progress.

Cyanide Potassium and Iron and Steel.

The effects of cyanide potassium on iron and steel are interesting to a high degree. Machinists use two forms of this chemical—the ferro-cyanide, or yellow prussiate, and the fused white cyanide, with the iron removed, writes Albert D. Pentz in the *Engineering Magazine*. The effects of these two forms seem identical as far as the hardening of iron is concerned, and if they differ at all in effect, it is in the superior degree of strength possessed by the white cyanide. That a film of this substance melted upon the surface of a red-hot iron article can cause it to harden on the surface, which otherwise would remain soft after quenching, is a marvelous and a valuable fact. The question of how this is accomplished cannot be absolutely answered, but it can be conjectured to a probability. Cyanide potassium has a close affinity for sulphur—so great, indeed, that it will absorb that element from tarnished silver, for which metal, in turn, sulphur has so great a liking that its most attenuated vapors collect on spoons and other articles of plate from the atmosphere, forming a sulphuret in the form of a black coating on the surface. A great many of the smaller sizes of iron screw rods are coated with copper and some of them, at least, are merely treated in a solution of the sulphate of copper to produce this result. In this treatment, the sulphuric acid leaves the copper in the metallic condition on the rod and attacks the surface of the iron. Hence there always is a sulphate present under the copper coating thus produced on screw rods. In case-hardening articles made from coppered screw rods of the kind named, it is found that animal charcoal has not a sufficient effect on so much of the original surface as has had no cut taken to remove the influence of sulphur from it, but where there has been a considerable amount of that surface removed to a reasonable depth, and has thus exposed the iron beneath the influence of the sulphur, this charcoal prepares it to harden in a satisfactory manner. Now, it is found by experiment, where the surface of such a screw rod does not become hard after treatment with animal charcoal in the usual case-hardening process, that cyanide potassium will neutralize the sulphur and assist this kind of surface to become hard. This substance does not work very well when mixed with the animal charcoal in the hardening case, because it does not spread freely, but clings to the charcoal in a manner not clearly understood, and so closely that the metal under treatment receives but little, if any, of it. If the pieces be touched where needed by a piece of the cyanide as they are taken from the box to be quenched, it will serve. This is often not practicable, however, as in the case of a great quantity of small pieces which would cool too quickly for such treatment. In this case it is suggested that a quantity of cyanide be dissolved in water, making a strong solution, and articles be quenched in it.

To Pump Natural Gas from Indiana to Ohio.

It is announced that a company of capitalists, principally from Lima, with Dr. S. A. Baxter and Senator Calvin S. Brice as the leading spirits, has been formed for the purpose of conveying natural gas from the Indiana field to Lima and the different towns in that section of Ohio. The company, it is stated, has secured leases on over 10,000 acres of gas territory, located in Jay, Delaware, Blackford and Madison counties, and is still acquiring more, and expect to make the block 15,000 or 20,000 acres before it is through with this part of the scheme. Its object is to furnish gas to all the different companies who now have plants in operation, but are sadly in need of a supply. In the list is embraced the following cities

and towns: Dayton, Springfield, St. Mary's, Van Wert, Lima, Sidney, Piqua, Troy, Covington, Versailles, Bremen, Minster, Urbana, Celina, and two or three other places. By the leading lights of the big undertaking it is claimed that in these plants there is invested over \$5,000,000, and all are dependent for their supply of gas from the small area of territory in Auglaize and Mercer counties, the pressure of which has been reduced to a mere nothing, and is virtually exhausted.

As now mapped out, they will lay a 16-inch main from the field a distance of 35 miles, while the feeders from the wells will be 6 or 8-inch lines, and the aggregate will make 75 miles of pipe. In the consummation of this scheme it is estimated the cost will reach over \$750,000, and possibly \$1,000,000. They expect to begin work before long and diligently prosecute it until finished.

Experiments with Magnetic Concentration.

Dr. Wm. B. Phillips of the Tennessee Coal, Iron and Railroad Company described to the Alabama Industrial and Scientific Society at its recent meeting, the results of some experiments with magnetic concentration on samples of red fossil iron ore weighing from 1 pound to 3000 pounds. Conclusions as to the commercial aspect of the process cannot be based upon the results reached to the present time. Dr. Phillips in the last six months has made more than 100 analyses in connection with the subject, treating various ores on a scale of 3000 pounds in a Hoffman separator. The results justified the conviction that they could take an ore of 35 to 40 per cent iron and 30 to 40 per cent ferruginous sand, with which the real ore is mechanically mixed, and bring the iron up to 55 to 60 per cent, at the same time reducing the sand to 10 to 13 per cent. Acting upon the results reached the company decided to erect a magnetizing kiln for treating 125 tons per 24 hours. The foundations are laid, the designs for the crushing, sizing and concentrating plant have been made, and, if nothing interferes, it is expected to have the whole plant in operation by the middle of February or the first of March.

New Furnace Lining.

B. Richards of Swansea, Wales, is the inventor of an improved lining for blast, reverberatory and other furnaces used in smelting copper and other ores, says the *American Manufacturer*. It is intended to provide a means for preventing the metals penetrating the sides and walls, as is said to occur in the present construction of furnaces. In carrying the invention into effect, the inventor provides on the sides and walls a layer of asbestos, fixed in any suitable manner and of a thickness corresponding to the requirements of the furnace. The asbestos is sewn together with strings of osbestos to the shape of the furnace, and laid on the claw bottom and up to the sides of the furnace bridge and foreplates, and a layer of sand seven inches thick is placed on the asbestos and the sides to be clayed. By thus preventing the penetration of the metals into the walls, a great saving is said to be effected.

A Great Bridge.

A proposal is afoot for building an immense bridge over the Mersey, to connect Liverpool with Birkenhead. According to descriptions in the Liverpool newspapers, the bridge will be of the arched suspension type, in three spans, the roadway being suspended from an arch instead of the usual chain. Each span will have a clear waterway of 1100 feet, the center span having a clear headway of 150 feet above high water of ordinary spring tides. The designs of the structure have already been completed.

Useful Information.

Uses of Cotton Seed Oil.

Last year there were probably 1,250,000 tons of seed crushed. Out of this seed there were obtained 1,000,000 barrels of oil. Of this amount it is estimated by *Pharmaceutical Era* that 300,000 barrels are used in Chicago for making lard, and St. Louis, Kansas City and Omaha are credited with about 200,000 in making the same product. A comparison of the statistics of lard production and cotton seed oil consumption might show interesting results as to the composition of the former. About 20,000 barrels of cotton oil are used on the coast of Maine to pack sardines, and probably from 50,000 to 100,000 barrels are used by soap-makers in the manufacture of toilet soaps. About 250,000 barrels go to Rotterdam, Holland, for making butter, and large quantities go to southern Europe for mixture with the pure (?) olive oils exported from Marseilles, Trieste, and other Mediterranean ports. Although this oil is not to be preferred for illuminating purposes on account of its containing too much gum, considerable of the cheaper grades is used for such purposes. The use of this article upon its own merits is, however, rapidly increasing. It is already extensively used in Latin countries as a cooking grease, and several American manufacturers are advertising it for culinary purposes.

How Long Will Japanese Coal Last?

This is the title of an article in a Japanese contemporary which considers that Japanese coal will become exhausted in 25 years and 10 months. Taking the statistical returns of the yearly yield of coal in Japan from 1882 to 1891, 17,453,390 tons is obtained as the average annual yield. Estimating the average proportional annual increase at 13 per cent, it is calculated that in 1911 the yield will be no less than 303,347,350 tons. Proceeding in this way, the conclusion is arrived at that the total yield for 25 years to come, computed from the current year, will be 515,552,326 tons. As the latest figures given by the *Noshomusho* fix the capacity of the Japanese coal mines roughly at 759,720,000 tons, and the proportion available for practical purposes being, according to the experience of England, three-quarters of the total capacity, it follows that the actual amount of coal which the mines will yield for use is 369,790,000 tons. If from that amount be deducted the aggregate annual production in 25 years, reckoned from 1891, there remain only 54,237,674 tons. In other words, in January, 1916, there will remain to Japan a supply of coal only sufficient for ten months.

A New Annealing Furnace.

A. Beard, Cambridge, Ohio, is the inventor of an annealing furnace in which some radical departures from present methods of construction are introduced, says the *American Manufacturer*. It is designed especially for annealing light sheets of steel such as are used generally in tinned plate manufacture. The old practice of charging and drawing boxes through the doors at the side of the furnace is abandoned, the furnace being built vertically and charged in that manner. By a simple arrangement annealing boxes, together with their bottom plates and contents, are easily handled by two men. Manual labor and its consequent cost is very largely dispensed with. It is claimed that the furnace is economical in construction and maintenance. The design is adapted for using coal, natural gas, crude oil or fuel gas.

Improved Air Brake.

An improvement has been made upon their air brake by the Westinghouse people, by which greater pressure is exerted if the train be running at very high speed. In fact,

there is a valve which regulates the pressure to correspond with the speed of the wheels. As the velocity is reduced, the cylinder pressure is reduced. Some experiments were made not long ago with this improved brake on the Pennsylvania railroad, and the performance was highly satisfactory. A train was stopped in 971 feet from a speed of 60 miles an hour. The ordinary emergency brake required 1235 feet in which to stop the same train.

How to Catch Mice.

Take a jar or tin bucket and fill it about half full of water and place it where mice are in the habit of promenading. Take a board 18 or 20 inches long, one end of which lay on the floor or ground, as the case may be, and the other end on top of the bucket. Sprinkle a handful of oats over the water in the bucket. This will not sink, but will remain on top and hide the water from view. Now sprinkle wheat, corn or anything else that mice like on the board so as to entice them to the top, when they will see the oats in the bucket and jump in to get it and soon perish.

I have tried this plan with quite satisfactory results. The trap is always set, and, when a mouse once gets in, there is no getting out. Of course it should be noticed every day or two, and the drowned rodents removed. I have never tried to catch rats in this way, but think if a jar that would hold six gallons or more were used, the plan would prove quite satisfactory.

It is a much safer way than the use of "rough on rats" or other poisons, and is considerably cheaper than those notorious "champion liar" rat traps. Give the plan a trial.—Ohio Farmer.

How To Tell a Person's Age.

A German newspaper says the age of a person and the month in which he was born may be discovered as follows: First you ask him to go to the other end of the room, to prevent your seeing what he is going to write. Then you ask him to put down the number of the month in which he was born, and multiply the latter by two; add five to the sum and multiply the latter by 50; add his age to the product; then deduct 365 and add 115 to the remainder. Suppose he is 49 years of age and was born in February—the computation might stand thus: 2×2 equals 4, plus 5 equals 9, $\times 50$ equals 450, plus 49 equals 499, minus 365 equals 134, plus 115 equals 249. The last two figures indicate the age, viz., 49, and the first figure, 2, February, the second month of the year. You simply ask the person to state the result of the calculation, and then declare that he was born in February and is 49 years of age. Experiment with this as often as you please and it is sure to work, provided you do it correctly.

Hardening Plaster.

It is stated that French builders, who have carried the art of hardening plaster to where it is used for flooring, either in place of wood or tile, employ for this purpose six parts of good quality of plaster intimately mixed with one part of freshly slaked white lime finely sifted, says the *Tradesman*. The mixture as thus composed is laid down in as quick time as possible, care being taken that the trowel is not used upon the surface for too long a time; after this the floor is allowed to become very dry, and is subsequently saturated in a most thorough manner with sulphate of iron or zinc, the iron giving the strongest surface, its resistance to breaking being found to be 20 times the strength of ordinary plaster. It appears that with sulphate of zinc the floor remains white while when iron is used it becomes the color of rusted iron; but if linseed oil, boiled with litharge be applied to the surface, it becomes of an attractive mahogany color, this being especially the case if a coat of copal varnish is added.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Sells suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen.
First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vibration and loss caused by the frequent breaking of the flange of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight riffling surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the edges and forming channels through the center. These slight rifflings also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

THE GRIFFIN MILL.

A perfect pulverizer of all refractory substances by either the wet or dry process. It works better and at less expense than any other Mill, and is conceded to be the only perfect pulverizing Mill Manufactured.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning.
The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less consistent writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with Illustrations, well bound in cloth, 1889. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion; Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volta's Method; Manby's Method; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new original and exact, as is also one of the processes for Zinc. The book contains 161 pages with Illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

Electricity.

A Chance for Inventors.

A prize of \$50,000 has been offered by the Metropolitan Traction Company of New York City for a system of street-car propulsion which will be superior or equal to the overhead trolley, without possessing the objectionable features of the trolley for crowded thoroughfares. The president of the company, John D. Crimmins, says that the general idea is to encourage some sort of underground trolley system.

The proposition was embodied in a letter sent to the State Board of Railroad Commissioners, and reads as follows:

"On streets where the lines are straight and the business is heavy the cable system is the most economical yet invented. For general use in a city, winding about through the streets following the routes of travel which the public wish to pursue, it is impracticable. You require straight routes for cable roads. We have, in addition to the lines upon which the cable will be laid, over 80 miles of street railroads now operated with horses, all below Central Park. It is to these lines in particular that we now desire to direct your attention.

"Up to the present time the only system whose practicability has been demonstrated is the overhead trolley. We are well aware, however, that its application in the streets of New York would not meet with the approval of the community. What we most desire now is to hasten the development and perfection of a better system. We therefore submit the following proposition:

"First—We will set aside the sum of \$50,000 to be awarded as a prize to any person who shall, before March 1, 1894, submit to your honorable board an actual working system of motive power for street railway cars demonstrated to be superior or equal to the overhead trolley.

"Second—The qualities necessary to meet this requirement shall be left to your decision; but with the present state of art, a system to win the award must necessarily approximate the trolley as a standard of economy in operation, but should be without the features objectionable to the public that are in it.

"Third—We shall exact no rights in the invention in return for the \$50,000, and shall have nothing whatever to do with the making of the award further than to pay any expenses which your honorable board may deem it necessary or wise to incur, either in the employment of experts, the giving of hearings, or the conduct of experiments—this in order that no effort may be spared to achieve the desired result."

Artesian Wells for Electric Lighting.

The cities and towns that are not fortunate enough to be near a flowing stream, or so situated as to be easily reached by coal cars, have another resource for power. Artesian wells furnish the means, and experiments in South Dakota have shown that they are not only an excellent source of power, but that they are economical and inexpensive to maintain.

Near the city of Redfield, S. D., what is known as the Hassell-Myers artesian well has been furnishing sufficient power to serve the needs for lighting the city, reports the *Electrical Review*. It was originally intended for irrigation purposes, and the cost of its simple construction was \$3000. Sinking to a depth of 1030 feet, the bore of the well is lined with piping from top to bottom, while outside of this six-inch pipe, extending from the surface down through the drift for a distance of 150 feet, is an eight-inch pipe which serves as a strengthening casing. The water comes from a stratum of clear, white sand, and is soft and clean. The flow is 2027 gallons per minute, and the entire volume of the water is thrown 16 feet above the pipe. From a two-inch opening the wa-

ter is thrown 158 feet into the air. The closed pressure of the well is 165 pounds to the square inch, and with a two-inch pipe the pressure is 128 pounds, while with an opening three-fourths of an inch larger, it is but 95 pounds.

With a home-made water wheel 50-horse power is being developed, and the Pelton Wheel Company claims that with their wheel at the 2½-inch opening, the well will be good for 100-horse power. At the present moment two dynamos are installed, and furnish current for the city for both arc and incandescent circuits. The lights are remarkably steady, and there can be little doubt of the success of the experiment, if it may be so called.

One mile from this well is another of smaller diameter, but of equal pressure. The sand formation in which the water is found crops out at the base of the Rocky mountains, and also in the beds of the Upper Missouri and Yellowstone rivers. If such be the state of affairs and the beds are the same stratum, the supply of water would be comparatively inexhaustible.

Wells could be sunk in hundreds of places in the vicinity of Redfield, and the water thus obtained could serve as the power for numerous isolated plants. The wells now in existence have been flowing for nearly two years, and no diminution of the supply is apparent.

Here, then, is a fertile field for small and even large manufacturers, and if the industry is successfully managed great inducements could be offered.

The owners of the plant state that it pays a yearly dividend of 15 per cent on an investment of \$15,000. The prospect is glittering enough. Who could ask for more?

New Electric Locomotive.

An electric locomotive of 1000-horse power is reported to be under construction in London from the plans of Sprague, Duncan & Hutchinson to the order of the North American Company. It is intended for slow speed and heavy traction in switching service. The machine is carried upon four pairs of driving wheels, all coupled. The frame is of steel, with deep pedestals. The 56-inch wheels are close-coupled; the first and last pairs only are flanged. There is a motor in each axle, the weight of the armature coming directly on the wheels, and that of the field magnets is on the journals through the pedestals; no spring supports are used. The four motors all form parts of a complete system on a rigid wheel base of 15 feet. The motors are of the alternating type, are wound for 860 volts at 225 revolutions, which will be the equivalent of 35 miles an hour when in multiple.

Blackness of Lamp Bulbs.

Stuart Smith, writing in the *Electrical World*, attributes the blackening of the bulbs of incandescent lamps entirely to a distillation of the carbon, holding that it cannot be due to a combination of the residual vapors in the lamp with the carbon, and a subsequent decomposition of these on coming in contact with the walls, because dissociation is never produced by cooling. The greater rapidity of deposit in new lamps than in old ones he attributes to the glass being a better condenser, when clean, than after a certain amount of deposit has taken place.

Electrocution for Animals.

Electricity is now being utilized for killing homeless dogs and cats at Hartford, Conn., says the *Chicago Journal of Commerce*. In the rear of the police station there is a cage just large enough for a dog to stand in, fitted up with electrical connections. The fore feet of the animal rest upon one electrode and his hind feet upon another, and when he is in position an electric current is switched on and he is put to death on the same principle as criminals are executed.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

STROCK THE LEDGE.—Amador Ledger: The Hardenburg mine, which was on the verge of shutting down upon the 1st of December, did not do so, and since that time has encountered the much sought-for ledge in north drift at the 800 foot level. For some weeks they have been following up the ledge which they first struck as a small stringer, and now it is between seven and eight feet in width. Charles D. Lane, who handles the property for the partnership, was here last week and brought Tom Pollen of the Altaville foundry over to look at the mill-site and give an estimate of the cost of the construction of a new hoist. Already several extra men have been put to work, though they are still drifting along the ledge. The rock taken out is put in the ore bins and the mill will probably be started up as soon as the new hoist is in place.

The following were elected trustees at the recent annual meeting of the Kennedy Mining Company: John Barton, president; D. E. Hayes, vice-president; John Taylor, F. Reichling and W. W. Belsbaw; L. F. Reichling was chosen secretary and J. F. Parks superintendent. For the fiscal year ending Nov. 30, 1893, the mine yielded 35,668 tons of ore. The face value of the gold bullion after paying cost of assay and express charges to San Francisco was \$646,552; dividends, \$460,000.

H. D. Emerson has arranged to work at mining in the Gwynn canyon during the balance of the winter and the coming spring.

Butte.

BRISK FORBESTOWN.—Grass Valley Union: Forbestown, in Butte county, is now quite an important mining town. The Bullion Consolidated and the Mt. Hope mines will both start up ten-stamp mills in a few days. These will make six mills running in the Forbestown district, with a total number of 110 stamps, and two big chlorination works.

VALUABLE DISCOVERY.—Oroville Register: R. W. Miller & Co. have struck a mine near Oroville that promises to rival any in the county if it develops as well as it now prospects. The shaft is only down 15 feet, but neither side touches the edge of the lode, so that the ledge is wide. The quartz contains considerable free gold and is rich in sulphurets. Mr. Miller is a miner of many years experience, and 30 years ago mined in this vicinity. Since then he has been in Colorado. The ledge is three or four miles up the river on the east bank. It is a matter of significance that the lode is directly opposite the famous Banner mine. Mr. Miller and his partner are working energetically to open up this quartz deposit and bring to light its hidden riches.

A LIVELY DISTRICT.—Forbestown New Era: The Standard mill in Oregon City is running on excellent ore and making big clean-ups. It is reported that the sulphurets from the ore upon which this mill is running assays as high as \$1000 to the ton, and that as much as a ton has been obtained from a single day's run. There are two other quartz mills in that vicinity paying well. Work has been commenced upon the old Banner mine. New and improved machinery is being put in the mill, and it will soon be in operation again. The company now owning the Banner are heavy capitalists, and it is their intention to work the mine mill for all there is in it. In early days several hundred thousand dollars were taken from this mine, and there is every reason to believe that there is just as good ore in the ledge as has ever been taken from it, and we expect in a short time to hear of big strikes being made.

TO BE SOLD.—Oroville Register: It is confidently stated that the Banner mine is soon to be the banner mine in Butte. The ledge has been sold to an English syndicate and active work will soon be commenced. As an indication of this, we learn that a contract has been let for cutting 1000 cords of 4-foot wood. The recent discovery of extremely rich ore in the mine led to the reported sale.

SHUT DOWN.—Deadwood Cor. Mercury: The Rainbow mine has been shut down for the winter, as it is inconvenient to handle the water with the machinery which they have at present. It is reported that the company will resume operations next spring, and sink the shaft 200 feet deeper. The ledge is not undeveloped, and the work on the mine has been prosecuted with a determination and management that will make it a success if there is anything in the ledge to warrant it.

Calaveras.

THE NORTH STAR MINE.—Prospect: The owners of the North Star mine, otherwise known as the Maguire mine, in Happy Valley near Mokelumne Hill, have made extensive preparations and are now ready to prosecute work on a large scale. It is the intention of the company for the present to work the mine by the hydraulic process, so that all the old drift works and caved ground extending back for about 300 or 400 feet can be washed off, after which it will be worked by drifting and milling. There is about 60 feet of blue gravel which prospects well throughout, and recently our reporter was shown some "chips" taken from this gravel valued at from \$20 to \$40 each. About 3000 feet of bedrock flume, lined with five-inch blocks, have been laid, extending from the mine down Buckeye gulch, and about 900 feet of 11-inch hydraulic pipe have also been laid. A No. 2 giant will be used and about 400 inches of water will be run under a 225-foot pressure. A blacksmith shop, store-room and changing-room for the miners have

been erected and everything is now ready for a start as soon as the decision of the Debris Commission is received, application for a permit to run having been made some time ago. There is no doubt but that the application will be granted, as the tailings will be run on ground where they can be easily kept back. The mine is under the efficient management of C. M. Burleson, a mining engineer, and one who has had extensive experience in both hydraulic and quartz mining in this and other counties of the State, and the work is under the foremanship of A. and W. W. Cook, two of the veteran hydraulic men of the county.

The North Star is one of the best-known mines in that district, having been worked for years on a small scale, but the greater part of the mine yet remains untouched. On several occasions different parties endeavored to purchase the property, but Mr. Maguire, the former owner, would not part with his "bank," as he called it, upon which he could always draw when he needed money, until about three or four months ago he finally concluded he would sell and the mine was bought by Messrs. Haven and Ewing of San Francisco, who now own the same.

Nevada.

A GOOD CLEAN-UP.—Telegraph, Jan. 5: Today a clean-up of 110 loads of ore was completed at Joe Southern's mill, and the yield was about \$30 per load, or \$3300, not including sulphurets or headings. The ore was from the Wisconsin mine, and was taken out by Messrs. Henley & Co., who have the mine leased. The rock came from the depth of about 200 feet. There is more good ore in sight at the Wisconsin.

A NEW ROAD.—Transcript: Fred Zeidler and Chris Mallon have returned from North Columbia, where they have been looking up, for San Francisco parties, a site for a new road to commence at the Bloomfield stage road on Grizzly Hill and connect with the Lake City road at North Columbia. If right of way can be secured, a road will be built which will be of great benefit to the people of the ridge. It will shorten the distance by the present road by way of the Purdon grade seven miles. This will enable teams to leave Nevada City in the morning and deliver freight at the St. Gothard, Delhi, Grizzly Ridge, West Delhi, Cornow, Eclipse and other mines in that district the same day. As the mining outlook is very encouraging in that section a road is very much desired. With the exception of one party the right of way has been secured.

MINES CLOSED DOWN.—Transcript, Jan. 4: The West Harmony and Odin gravel mines and the Federal Loan quartz mine had to suspend operations to-day, on account of the water in their ditches freezing. To-morrow steam power will be used at the Odin and West Harmony and work will be resumed.

THE HOME MINE.—Transcript, Jan. 3: The shaft at the Home mine, on Deer creek, is down 120 feet. It will be sunk 250 feet before any drifting will be done. At present the ground is very hard and the quantity of water great.

THE CALIFORNIA.—Transcript, Jan. 5: The Gaston Ridge Mining Co. is repairing the mill at the California mine, in God's Country, and putting it in good order, so that it will be ready to run as soon as there is rock from the mine to crush. Men are also engaged in clearing out and putting the mine in shape to resume operations in a short time. At present there are 12 or 15 men employed, but the force will be increased as rapidly as room is made for more men. It is the company's intention to open up the mine thoroughly and work it on a large scale.

COL. C. W. TOZER, the superintendent, informs us that as soon as spring opens the capacity of the mill will be increased by the addition of 20 stamps more. Steam is the motor that has been used to run the mill. This will be changed when the mill is enlarged, and either water-power or electricity substituted. If the former is used the power will be transmitted from the water-wheel to the mill by means of a long wire cable. Should electric power be decided upon, and Col. Tozer thinks very favorably of this scheme, the necessary current can be easily generated by water-power and transmitted to the mill. If they use electricity it will be an innovation in this county in the way of power for mining purposes.

THE SEASTAPOL.—San Francisco Call: Mr. E. H. Baxter, the mining operator, has handed the Sebas'apol mine at Grass Valley. This property was worked by the Watt brothers to great advantage in early days, when a fire destroyed the mill and hoisting works, and the property has remained idle ever since. It lies on the same ledge as the Empire and other noted mines, and it is the intention to open up the mine and thoroughly prospect it at an early date.

Placer.

CRUSHING ROCK.—Republican: The new mill at the Three Stars mine is now crushing rock, and thus one of the most important mining enterprises in this part of the State has been entered upon. This mill is one of the finest in the State, and the property on which it is situated gives great promise of a future yield of the yellow metal. Success at the Three Stars means prosperity for the mining interests of the Ophir district.

MINES PAY WELL.—Colfax Sentinel: The mine on Bushy, near Forest Hill, owned by Mr. C. Albrecht and others is paying very well. This mine is located near the one of Cranage & Federer, and is becoming quite celebrated for its richness.

The Gold Ring mine at Green Valley promises very well. It is expected the mill will be all ready for work in about a week. Several nice specimens of cement have been taken out in excavating for the mill, and much finer ones are expected when the work in the main part of the mine is begun.

The Golden Eagle at Shady Run is also push-

ing ahead. At present a new tunnel is being run to tap the gravel, so that it may be worked to better advantage. It is expected the tunnel will be finished and gravel be taken out within two months.

The Redstone quartz mine at Blue Canyon has resumed work, and it is now being worked in a systematic way. A good company has the mine hooded and expects to develop it into a good property.

The Paragon mine at Bath laid off quite a number of men Christmas, but it is expected they will soon be put to work again.

The Mayflower mine is working a full force of men and is paying as well as ever.

The Dardenelle mine prospects well, but some trouble with the machinery has been had of late that has interfered with its working. It is all right again, and the mine will soon begin to pay as well as formerly.

The Big Dipper mine at Iowa Hill is rapidly developing into one of the best drift mines in the county. The gravel is rich and the machinery works splendidly. About 40 men are employed at present.

Considerable development is promised in the Black Canyon section and near Sailor Canyon and Bald Mountain the coming summer. In fact, everywhere throughout the mining sections of Placer there is a renewed activity and an increased interest in mining properties.

ANOTHER DIVIDEND.—Colfax Sentinel: The Morning Star mine at Iowa Hill declared another dividend of \$3 a share last Wednesday. This is dividend No. 37, and is but in keeping with the mine's past record. There are about 40 men working at the mine at present, and the indications for the future are bright indeed. This mine pays out about \$3500 every month in wages. This for a year is equivalent in value to about twice the entire amount of fruit shipped from Colfax last season.

Plumas.

WITH REDUCED FORCE.—National-Bulletin: Work at the Crescent mine continues with a reduced force. There is nothing new in connection with the property to report.

At Green Mountain 30 stamps are crushing ore steadily, with fair results.

Considerable prospecting is going on between Green Mountain and Round Valley Reservoir, and some important developments have been made, which we will note later on.

Work on the Kellogg property, below Elizabethtown, is progressing favorably. The hoisting works of the Loring & Leavett mine have been taken down and moved, and the work of rebuilding is now in progress. Probably less than ten days' good weather will enable them to get under cover.

A. B. White, superintendent of the Quincy Mining and Water Co., was in town Wednesday. Work on the big dam will begin in a few days, and when finished everything will be ready to begin mining when the water season opens.

Sierra.

GONE TO WORK.—Messenger, Jan. 6: John and Louis Bernhardt have gone to work at the Oxford (old Good Hope) quartz mine, a couple of miles above town. This is known to be a good mine, but the financial circumstances of the owners forbid its proper development at the present time.

It is rumored around town that the men at work under Mrs. Kenn's restaurant, on Main street, have struck a pretty good piece of ground. Jack Woodside and Dick Osborne are running the mine and have four hired men. They work two shifts. In early days the ground under Main street, as far as worked, was enormously rich, but on account of lack of grade to drain the water very little of the channel could be worked.

Tuolumne.

RICH STRIKE AT RAWHIDE.—Amador Ledger, Jan. 5: Jas. E. Dye, of the Amador gold mine, drove over to Sonora about Christmas time and spent holiday week with his friends, the Nevills, at the Rawhide mine near that town. He says that they have struck it rich in that mine. In the 400-foot level a vein of quartz was struck which prospecting well, and when it was again encountered on the level below, it was four feet in width and immensely rich. They are running ten stamps at present, but will start more as soon as a plant for saving the slimes, upon which they are now at work, is completed. The Rawhide was one of the early-day gold producers and lay idle supposedly worked out for many years until Nevills, Ballard and Martin took hold of it about three years ago. They have put a great deal of money into it and worked faithfully until rewarded with a remarkably rich development. Besides the rich ledge of rock which is above referred to, they have opened up and prospected a 30-foot ledge which in free gold mills \$10 per ton. Besides the Rawhide, Mr. Nevills is opening up the App and the Alameda, both in the same section of country. In the former he has found a ledge which produces \$50 to the ton. Mr. Nevills has surely made a great strike in Tuolumne county, and could doubtless close out his interest there now for a million dollars. He is now considering the advisability of reopening work in the Mammoth tunnel and also at the Moore mine near this town.

NEVADA.

Washoe District.

SUMMARY OF CUMSTOCK OPERATIONS.—The report of Superintendent Lyman of the Consolidated California & Virginia mine, for the past week, says: "1650 level.—In our workings in and from the drift run north from the foot of the npraise which was carried up from the sill floor of this level, we have been engaged during the week in retimbering and prospecting without extracting any ore. Have also employed the time in the vicinity of the winze (20 feet

down) sunk from the west crosscut from the main northwest drift in timbering and prospecting. The southwest drift (the Rule drift) from the 1000-foot station of the Consolidated Virginia shaft, has been advanced during the week 60 feet; total length, 265 feet; face in porphyry somewhat harder and clay with streaks of quartz."

Superintendent Kervin reports as follows of the work on the 900 level of the Best & Belcher mine: "900 level.—The east crosscut on north line has been advanced 25 feet; total length, 535 feet; face in hard porphyry."

On the 1465 level of the Ophir mine, the north drift from the west crosscut is out 42 feet. The face is in porphyry and clay separations. In the Mexican Mine, on the 1465 level, the west crosscut from the south drift from the top of the npraise is to 88 feet. The face is in porphyry formation with clay separations. On the 900 level of the Union shaft the Sierra Nevada and Union Con. joint north drift from the joint west drift is in 344 feet. The face is in porphyry and clay. On Cedar Hill the Sierra Nevada south intermediate drift is in 350 feet. The face is in porphyry. At the Andea mine, on the 420-foot level, they are preparing to drift north in the ore formation lately encountered in the west crosscut. In the Gould & Curry mine, on the 200 foot level, west crosscut No. 5 is out 329 feet. The face is in hard porphyry.

In the Hale & Norcross mine on the 1300 level they continue stoping ore from the winze below this level and extracted during the week 23 cars of ore, assaying \$33.33 per ton per car sample, and 3 cars of ore, average assay per car sample \$14.97 per ton. In the Chollar mine they are making repairs in main shaft below 850 level. Extracted and sent to the mill the past week 162 tons and 800 pounds of ore from the 100 level. Milled during the week 112 tons. On hand at mill, 107 tons. Average battery assays, \$29.11; average car-sample assays, \$33.99; bullion shipped to Carson mint, 371 pounds. In the Potosi mine they have started an east crosscut 300 feet south of east line, 750 level, which is now out 30 feet; face in porphyry. The south drift, 200 feet east of Potosi winze, 1100 level, is out 205 feet; face shows porphyry. Are repairing the south drift, 930 level, and making some repairs in the Potosi winze below the 1100 level. At the Ward shaft the west drift from the station, 520 level, is out 425 feet from the shaft; face in clay and porphyry. At the old Alphashift, repairs are still being made.

OREGON.

THE MOUNTAIN LION.—Jacksonville Times, Jan. 4: The company now in charge of the Mountain Lion mine, in Josephine county, has run a 120-foot tunnel since Dec. 1st. They are running day and night and taking out considerable ore of a good quality.

The Ashland Mining Co. has resumed operations on their 600 foot tunnel, upon which work was stopped last August on account of scarcity of water. They are running the Burleigh drill steadily and expect to reach the ledge in February.

The mine in Josephine county, of which a three-fourths interest is owned by Deyoe, Brown and Hand, is to be developed. Those gentlemen have bonded their interest to a Mr. Murray for \$30,000. J. W. Brown and son and Louis Dyer will go out from Albany to commence operations for Murray at once.

It is said that a ten-stamp mill will soon be put up by J. C. Lawis, the Portland mining man, on the Green quartz mine on Galice creek. This mine has been worked occasionally for the past 18 years, and has proved to be a paying property.

Work on the Mountain Lion mine is being pushed vigorously. A new quartz mill will soon be placed in position, to take the place of the arrastra now in use. First-class ore is being taken out.

Messrs. Boynton, Razee and Tohler of Grant's Pass, who have been prospecting the old Thompson creek ledge, have received sufficient encouragement to put up a five-stamp mill, which is expected to arrive before long. They have struck a well-defined and rich vein of quartz.

THE WHITE SWAN.—Baker City Democrat, Dec. 25: In conversation with Mr. Tarbell, who is the owner of a one-third interest in the property, he stated to a reporter that there was no reason to withhold the amount of gold produced by the White Swan from the public and he thought that as a matter of justice to the mining interests of the county the public ought to know. The last output was referred to and Mr. Tarbell stated that the amount was \$4000, the result of a run for eight days. In other words the White Swan was turning out bullion at the rate of \$500 per day. The ore bins are full of this kind of ore and the mine according to Supt. Nivens' report never looked better than at the present time.

WORKING THE TAILINGS.—Rogue River Courier: Cheney, Spencer & Hayes own a paying placer mine about a mile from Waldo. They are working 50 acres of tailings which are estimated to be worth \$100,000, as the early-day miners were not very careful about picking up the fine gold, and even let a good many good-sized chunks of amalgam run over their rifles.

ARIZONA.

THROUGH GOLDFIELD CAMP.—Yuma Times: We visited the Geneva mine, where about 26 feet of work is done, showing very good quality of ore. From there we went to the Prospector, where about 18 feet of work has been done. Next to the Refusal; this is the complicated ledge carrying gold, silver and galena. Here 40 feet of work has been done, showing a 65-foot vein. From thence to Needle, which has a 100-foot vein, which assays \$10 to the ton across the 100 feet of ledges. Mr. Leach of Tombstone is interested in this claim. From the Needle to the Emerald claim, where the

Pomeroy hoye have done considerable work. Thence to the Treasure Vault. Mr. McFarland and Mr. Coewell, who are interested in the claim, panned out a little gold, some of it quite coarse, to show us what they had. They have done considerable development work and it shows for itself. We went over to Mr. Pomeroy's High Flyer claim and found a lot of work done in cutting and sinking. From there we went to the Sylva claim. Here we found a fine foot wall, which can be traced for some distance on the surface. The claim has had but little work done on it, but the first of January it will be developed, when it will count on assessment work. From there we took in the Black Queen, belonging to the Mammoth Mining Company.

LITHOGRAPHIC CLAIMS RECORDED.—Arizona Enterprise, Jan. 4: Mining locations for a group of five claims, the same from which the lithographic samples have been on exhibition in this city, were filed yesterday in the county recorder's office. They consist of the Lithographic, entered in the name of B. Robles; the Quarry Group and the Side Quarry, in the name of L. Snaetegui; the Winall Quarry, W. A. Dalton; the Lithograph Quarry, Adolfo Vasquez; and the Cardwell Quarry, Wm. J. Jones. These claims lie two and one-half miles south of Arivaca, on the Oro Blanco road.

GETTING OUT GOOD ORE.—Mohave Miner, Jan. 7: Al Ross and Charles Mackenzie are working on the old Rawhide mine and are getting out rich ore. There is over 1000 tons of ore on the dump of the mine that will run over one hundred ounces in silver that is perfectly free milling. If a mill was put up in that country plenty of ore could be had to keep it running all the year round. Two sacks of ore in a recent shipment from the Rawhide mine netted the owners over \$1300.

Chicago parties are talking of putting a mill at Stockton Hill. The right kind of a plant would pay well.

One of the mines at Ferguson has just been sold for about \$150,000. It is a good property. Reports from Tomahstone give a rather gloomy account of affairs in that place. Nearly all the mines have closed down because of the constantly decreasing value of silver. Last week the only mine employing men shut down and put on a watchman.

J. A. Healy, F. A. Healy and Charles Price have bonded five copper properties on Bill Williams' fork to Eastern parties for one year. Five thousand dollars has been deposited in bank with which to commence development work. The mines show up well in copper on the surface, and if they develop well a smelter will be erected on the ground.

MONTANA.

THE FIRST ORE TRAIN.—Butte Inter-Mountain, Jan. 3: Work was resumed in earnest on the Anaconda Hill to-day. The Green Mountain, High Ore, Anaconda, St. Lawrence and Mountain Consolidated mines are all at work again. At the latter mine the full force was not put on to-day, but Larry Manning, in charge there, said they would be raising ore to-morrow.

Some repair work on the ore chutes and in the mine are going on. This mine had 400 men at work during November. The first train-load of ore over new B. A. & P. railway was made up at 3 o'clock to-day from the Green Mountain and Anaconda mines. It consisted of 75 carloads.

All is lively on the hill to-day. Business men say hundreds of miners have been buying boots and coats, etc., for underground work. It is expected before to-morrow morning 175 carloads of ore will have been shipped over the new line.

FOR A LONG TUNNEL.—Butte Inter-Mountain: The Bi-Metallic Company is advertising for bids, to be submitted January 15th, for driving and timbering a drain tunnel about 6170 feet long from the west face of the 1000 foot level of the Blaine shaft to Boca on Douglas creek. The first tunnel is to be 2075 feet long and the second 4106 feet long, each to be four feet wide and eight feet in the clear. No bonds will be required from the contractors, but the company will hold back a percentage of the estimates. Cessation of work five days will be deemed abandonment, and the company reserves the right, on 20 days' notice, to terminate the contract by purchasing the supplies the contractors may have on hand. All ores extracted in the work shall be the property of the company. It is required that three crews of miners be employed to drive the cross-country tunnel.

The company will furnish, free of charge, hoisting engine and hoilers, air compressors, all pumps, cars, rails and ties, timbers framed and drain boxes ready to put in, at the Parnell and Bi-Metallic Extension shafts. At Boca the company will furnish, free of charge, hoiler, air compressor, machines, cars, rails, cross-ties, timbers framed and ready to put in. The company will furnish at cost drill steel for machines, powder, fuse, caps, candles, picks, hammers, shovels and any other tools needed, also wood, oil, etc., payment for same to be deducted from monthly estimate.

Complimentary Samples.

Persons receiving this paper marked, are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

An attachment for \$3000 has been obtained in New York against the Prescott & Arizona Central Railway Company in favor of Miles O'Brien and James Cannon, as receivers of the Madison-square bank, for unpaid interest on \$100,000 of the company's bonds held by the bank.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

ELEVATOR.—William B. Morris, Seattle, Wash. No. 511,447. Dated Dec. 26, 1893. The object of this invention is to provide an elevator with a novel means for moving the cage or platform up and down. It consists essentially of short-jointed bars connected together and acting to push the cage or platform up or allow it to be depressed. These short bars fit around a rectangular drum at the bottom, around which they fold in the same manner that rope coils upon a round drum when the elevator is down. When the elevator is to be raised, it is forced up by rotating this drum so as to uncoil and extend these jointed links which move up in suitable guide channels in the sides of the elevator shaft, and thus serve to push the elevator up.

CHANDELIER CAR LAMP.—Emile Boesch, San Francisco. No. 511,338. Dated Dec. 26, 1893. This invention relates to improvements in car chandelier lamps. Its object is to provide an oil lamp fixture having an argand burner with a closed air chamber below, receiving an air supply through conduits from above or on the outside of the roof or ceiling from which the chandelier is suspended, a means for more perfectly regulating the draft and the escape of products of combustion, thereby giving a better light with the same size of wick, avoiding smoke and smell and the blowing out of the flame by sudden gusts of wind, and for opening or cutting off the oil supply from the reservoir. This is all carried out by details of construction which are not easily explained without illustrations.

AUTOMATIC DELINEATING MACHINE.—Fred Bangerter, S. F., Cal., assignor to the Automatic Novelty Manufacturing Company. No. 512,089. This invention relates to an automatic mechanism by which stated figures can be marked, written, drawn, or engraved, and may be used to either make letters, draw figures, or engrave upon surfaces. For purposes of amusement the apparatus is enclosed in a figure, the hand of which carries the delineating instrument, and when the apparatus is set in motion it moves the hand so as to write the letters or make the figures or delineations required. It consists of a series of gears, came and connected levers which are actuated thereby so as to produce the desired letters or figures.

PIANO.—Henry Muller, Stockton, Cal. No. 512,048. This invention relates to improvements in pianos, and its object is to provide a means for fixing the sounding-board to the iron frame so as to obtain the best resonant effect, a means for holding the tuning pins in the frame and automatically keeping them tight, and a sounding-box or resonance conductor within which the ends of the strings opposite to the tuning pins are secured, this box serving to increase the resonant effect of the strings. It also relates to an improved agraffe and adjustable dampers which are applied to the strings as occasion requires.

PNEUMATIC BRAKE.—Francis M. Speed, S. F., assignor to the Pneumatic Brake Company of same place. No. 512,233. Dated Jan. 2, 1894. This invention has for its object the efficient, safe and economical use of compressed air for the purpose of applying brakes. It consists of a braking mechanism on the car, a brake cylinder for operating it, a main reservoir on the car in which air under high pressure is stored, supplementary reservoirs also on the car adapted to receive air under different pressures, outlets from the supplementary reservoir connected with the brake cylinder and a multiple way cock common to all said outlets, whereby air under different pressures may be admitted to the brake cylinder.

AIR AND WATER PURIFIER.—Dr. C. F. Buckley, S. F. No. 511,995. Dated Jan. 2, 1894. This device consists of a reservoir or tank for the water, having an inlet and an outlet, an air disinfectant and an automatically operating connection between said air disinfectant and the reservoir or tank, whereby the water in the reservoir is subjected to contact with disinfected air only. The object in view is to avoid contamination of water by non-disinfected air, and to provide simple and effective means for this purpose, adapted to be used by every household.

METHOD OF UNITING METALLIC SHEETS.—James Gould, Jr., Oakland, Cal. No. 512,021. Dated Jan. 2, 1894. This method consists first in overlapping the adjacent ends of the sheets; second, forcing from one side both thicknesses of metal to form protruberances or bulging portions on the other side, severed from the metal on their sides and remaining joined thereto at each end; and third, altering the superficies of one part with relation to the superficies of the other, whereby the parts are prevented from returning to their first position.

PUMP ENGINE.—Levi Holben, Sacramento, Cal. No. 511,426. Dated Dec. 26, 1893. This engine is simple, compact and effective, being especially adapted for pumping purposes, as it provides for a constant and equal flow of water. It consists of a cylinder seated on top of the pump pipe. The piston rod is connected directly with the pump rod, and the piston has also a stem extending upwardly through the top of the cylinder. Upon the side of the base of the cylinder is a valve which controls the inlet and exhaust passages under the piston. The

valve is operated by connections with the upper piston stem or rod. The stem lifts the piston, the latter returning by the weight of attached parts. Upon the piston rod is a displacer operating freely in the upper end of the pump pipe, whereby a constant flow of water is had.

HAIR-CLIPPING MACHINE.—Ole Olsen, Oakland, assignor of one-half to Charles Greene of San Francisco. No. 511,966. Dated Jan. 2, 1894. The essential novelty of this machine is a hinge connection between the handle and the center-head and suitable power transmitting connections which will act in any position of the center-head. The object of the machine is to adjust the center-head to varying positions, thereby adapting the device for the most convenient operation under all circumstances and in different places.

Coast Industrial Notes.

—All the shingle manufacturers in British Columbia have joined an association to keep up prices.

—The State Board of Examiners will pay no more coyote claims until a specific appropriation is made by the Legislature.

—The cold weather last week was a great boon to the "ice farmers" in the mountains. One company for the first crop harvested 3500 tons.

—So far, twenty-one sealers have left Victoria this season, being one-third of the entire fleet. They have carried with them 483 whites and 74 Indians.

—An exchange says that the locomotives of the Shasta division of the Southern Pacific are soon to be supplied with electric headlights. A motor will be placed in the cabs.

—A new receiver has been appointed to handle the finances of the Oregon Pacific Railroad Company, in place of E. W. Hadley, who resigned a few days ago. The new receiver is Charles Clark of Portland, Or.

—Official statistics, just compiled at Port Townsend, show 2350 Chinese passengers in transit from the Orient, by way of the Canadian steamers, landed in Portland and Astoria last year. With the exception of 500, all obtained admittance as merchants.

—The Pacific Coast Council of Trades, in session at Sacramento, has declared in favor of the municipal ownership of gas, electric light, waterworks, street railways, the nationalization of telegraph, telephone and railway lines, and postal savings banks, compulsory education up to sixteen years, and eight hours' labor a day.

—Two large ocean steamers are now en route from the Atlantic coast for Puget Sound; they will arrive there some time next month, and will carry passengers and freight between Sound points and San Francisco during the Midwinter Fair period. The vessels are said to be the property of the Canadian Pacific Railroad Company.

—The Governor has appointed the following delegates from the State at large to the Transmississippi Congress which is to be held in San Francisco: A. P. Williams of San Francisco, J. M. Walling of Nevada City, J. A. Louttit of Stockton, J. P. Widney of Los Angeles, Joseph Brown of San Bernardino, D. E. Knight of Marysville, Charles McCreary of Sacramento, W. D. Tupper of Fresno, M. A. Luce of San Diego and C. H. Phillips of San Luis Obispo.

—The reported consolidation of the Southern Pacific Milling Company and the Southern Mill and Warehouse Company is affirmed by Manager F. H. Wheelan of the latter corporation. The consolidation will now be known as the Southern Pacific Milling Company, with headquarters at San Francisco. The warehouse company's interests were confined to Santa Barbara and Ventura counties, with the central office in this city, while those of the other lay between Santa Margarita and Soledad.

—The preliminary work for the building of an electric road from Ione to Sutter Creek and Jackson, and the putting up of an electric light plant in conjunction with the enterprise, at Sutter Creek, are attracting a great deal of attention at present in Amador county. The latter will supply Sutter Creek, Jackson and Amador City with light, and the company has a water fall of 600 feet at the first-named place to supply the power. J. S. Emery and Abner Doble, of this city, are at the head of the new improvements.

—C. F. Crocker states that the question of beginning work on street railway extensions across the bay is under consideration. It is quite probable work will be begun shortly. The proposed extensions would add about three miles of track to the system owned by Southern Pacific officials in Oakland. The principal work would be the construction of an electric line along San Pablo avenue from the terminus of the cable road to University avenue, West Berkeley.

Another extension is the continuation of the cross-town line, which extends from Telegraph avenue to Larkin. This extension would be west on Alcatraz avenue to San Pablo avenue, where it would connect with the extension to West Berkeley. These extensions would make the means of communication in the urban territory lying between Oakland and Berkeley as complete as those which now exist in Oakland.

—The withdrawal of W. F. Whittier from the firm of Whittier, Fuller & Co., is announced. Official evidence of this fact is afforded by the filing of articles of incorporation of W. P. Fuller & Co. The directors of the new corporation are: W. P. Fuller, J. F. Littlefield, A. B. Perry, Margaret H. Fuller and Bertha A. Fuller. The capital stock of the new concern is \$2,000,000, all of which has been subscribed, as follows: W. P. Fuller, \$439,800; J. F. Littlefield, \$100; A. B. Perry, \$100; Margaret H. Fuller, \$1,120,000; Bertha A. Fuller, \$220,000; Ella F. Fuller, \$220,000.

—George G. Buckland has made application to the Board of Supervisors for franchises for an electric road over a large number of San Francisco streets. The cars are to be operated by the storage system, or by an underground wire, but not by trolley. Mr. Buckland pledges himself to begin work in thirty days, to spend \$50,000 in sixty days, \$200,000 in ninety days, \$500,000 in six months, and to have the whole road in operation in three years' time. In addition to the two per cent gross annually to which the city is now entitled from the earnings of a cable company, he offers to pay to the city five per cent weekly of the gross earnings as a bonus for a fifty-year franchise.

—The Folsom Telegraph learns that the big chute which has been under course of construction by the American River Land and Lumber Company during the past year is nearing completion rapidly. About 800 feet remain to be done. The chute is 3000 feet long, and the top of the same is 1200 feet higher than it is at the bottom. Logs 30 inches thick are used in its construction. There are seven of them—one forming the bottom and three on each side, making a V-shaped flume of it. Among the cribbing that has been built is one place over Slab creek, 200 feet long and 50 feet high. This is built up of solid logs placed one on top of the other. In this pile of logs there has been an opening left for the water of the creek named to flow through. This opening or water-way is 20 feet high and 10 feet wide, and all the water will go through it easily. The work will be finished some time in February, and as soon as possible thereafter the logs will be put into the chute and slid down to the river.

—Walter Cheadle, a Carson business man, in an open letter, advocates the building of a railroad from Carson to the Sacramento river, through Carson, Fredericksburg and Diamond valley, around the south end of Lake Tahoe, through Lake valley, then over the hill to Strawberry, down the American river to Placerville, and from there to the Sacramento river, putting the State in direct communication with the ocean and making Nevada a competitive point. He advocates the building of a road by the State by the issuance of three-per-cent bonds for \$3,000,000, redeemable in 50 years, with the Governor, Controller, Treasurer, Surveyor-General and Attorney-General as the board of directors. He advocates the formation of a new party, electing legislators on a platform which inflicts the death penalty on all who sell out to competing roads. He would make the Governor superintendent, with the power to appoint an assistant. He would fix the passenger rate at \$5 for a round-trip ticket to San Francisco, half a cent a pound the freight rate and \$10 for a carload.

—The Southern Pacific Company is about to get its Oakland street-car business together into more compact and systematic shape. Ever since the corporation bought James G. Fair's Oakland street-car lines, along with his narrow-gauge roads, its street railways across the bay have been owned by three separate corporations. It has been decided that it would be more convenient to have one company control all the lines and do all the business. In accordance with that decision, there have been filed with County Clerk Haley articles of the Oakland Railroad Company of San Francisco, which in the future will own the 12 7-8 miles of Southern Pacific street-car lines across the bay. There is \$2,500,000 worth of capital stock to declare dividends on. It is divided into 25,000 shares. The Directors for the first year are C. F. Crocker, H. E. Huntington, S. T. Gage, C. E. Green and F. S. Doughty, who have already subscribed for twenty-six shares of stock each. It is understood that no changes in the operation of the roads will follow.

Market Reports.

The Markets.

SAN FRANCISCO, Jan. 11, 1894.
The silver market during the week has shown improvement, both at home and abroad. Copper is weaker. Lead has again receded.

Quicksilver.

The receipts of Quicksilver at this port in 1893 were as follows:

Months—	1893.	1892.
January.....	2,243	1,701
February.....	2,388	1,543
March.....	1,588	1,875
April.....	1,623	1,901
May.....	2,511	1,598
June.....	2,790	1,614
July.....	2,014	1,632
August.....	1,919	2,013
September.....	1,281	1,753
October.....	2,718	2,171
November.....	2,352	1,881
December.....	2,617	2,004

Totals.....25,034 21,686
Against 14,556 in 1891, 13,130 in 1890, 15,705 in 1889, and 21,030 in 1888. As compared with 1892 there was an increase of 4,348 flasks in the past year.

EXPORTS.

The exports of quicksilver from San Francisco by sea during December, 1893, were as follows:

To—	Flasks.	Value.
Mexico.....	181	\$ 6,244
Central America.....	100	4,000
Australia.....	100	4,000
Hongkong.....	2,500	80,000

Totals.....2,881 \$94,244
During the twelve months ending December 31, 1893, the exports were as follows:

To—	Flasks.	Value.
New York.....	6,450	\$261,050
Mexico.....	3,899	159,592
Hongkong.....	3,800	122,000
Australia.....	1,250	51,325
Central America.....	794	32,033
Otario.....	280	11,200
New Zealand.....	87	3,384
British Columbia.....	11	476

Totals.....16,571 \$641,660
1892.....8,108 334,747

Increase.....8,463 \$306,913
In 1891 the exports by sea were 40,411 flasks, against 36,890 in 1890. The movement by sea in the past year was the largest since 1887, in which the exports were 18,619 flasks.

Mining Share Market.

SAN FRANCISCO, Jan. 11, 1894.

During last week Consolidated California and Virginia stock, which had dropped from \$6, the highest point of the late deal, to \$2.50, rallied to \$4.50, and the other leading stocks acted in sympathy. The reaction was not well sustained. Another decline came and Consolidated California fell to \$3.50. This occurred Friday morning at the Pacific Exchange. Then came another and a smaller rally, and Saturday morning California touched \$4, but afterward declined to \$3.90 and closed weak, as did the general Comstock market.

Monday of this week there were numerous small fluctuations in the Comstock shares, which made business quite active among the commission brokers. The regular chippers of the street took advantage of the opportunity to turn a nimble sixpence.

Tuesday the market opened quieter and prices had a weaker tone, under the sales of recent buyers. Con. California & Virginia opened with sales at \$4.35. After that there were small fluctuations in the leader and in the neighboring stocks, with much racing between the Boardrooms by small chippers.

Wednesday the Comstock market was active, with numerous small fluctuations in prices. Tuesday

afternoon there had been a weak closing, with sales of Con. California & Virginia at as low as \$3.90, and Wednesday morning in the Pacific Exchange that stock had a further decline to \$3.80. At the second session the market was of a fluctuating character, with alternate periods of weakness and strength.

According to the latest advices the southwest, or so-called "Rule" drift, on the 1000-foot level of the Con. California & Virginia mine, is out nearly 300 feet from the station of the old Con. Virginia shaft, and its face continues in the same formation as reported in Superintendent Lyman's last weekly letter; viz., harder porphyry, with small streaks of clay and quartz.

Cal. Debris Commission Notices.

THE CALIFORNIA DEBRIS COMMISSION having received petitions to mine by the hydraulic process, from Joseph Hustler, in the Hustler mine, near Cherokee, Nevada Co., and deposit tailings in an old hydraulic pit; from Olonzo Eggle, in the Pomroy mine, near Ono, Shasta Co., to deposit tailings behind dams in the Pomroy gulch; from the Columbian Cold Mining Co., in the Welch mine, near Michigan Bar, Sacramento Co., to deposit tailings behind a dam in a dry ravine; and from the Kate Hayes Mining Co., in the Manzanita and French Corral mines, near Sweetland and French Corral, Nevada Co., to deposit tailings in old hydraulic pits, give notice that a meeting will be held at Room No. 32, Food Building, San Francisco, Cal., on Jan. 23d, 1894, at 1:30 P. M.

Assessment Notices.

STANDARD GOLD AND SILVER MINING COMPANY. Location of principal place of business, San Francisco, Cal. Location of works, Butte County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 18th day of December, 1893, an assessment, No. 1, of five cents per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, Room 40, 320 Pine Street, San Francisco, Cal., or to the President, Tyler Beach, St. James Hotel, San Jose, Cal. Any stock upon which the assessment shall remain unpaid on the 28th day of January, 1894, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on SATURDAY, the 17th day of February, 1894, to pay the delinquent assessment, together with the cost of advertising and expenses of sale. By order of the Board of Directors, T. E. JEWELL, Secretary. Office—Room 4, 330 Pine Street, San Francisco, Cal.

FOR SALE OR RENT. THE TOSTON SMELTER.

Specialty adapted for pyritic smelting. Capacity 100 tons per diem. On the Northern Pacific R. R., within a few miles of the extensive gold deposits of Radersburg, St. Louis, Winston, etc. Apply

Manager TOSTON SMELTING CO., TOSTON, MONTANA.

DIVIDEND NOTICE.

THE GERMAN SAVINGS AND LOAN SOCIETY, 526 CALIFORNIA STREET.

For the half year ending December 31st, 1893, a dividend has been declared at the rate of five and one-tenth (5 1/10) per cent per annum on term deposits, and four and one-quarter (4 1/4) per cent per annum on ordinary deposits, payable on and after Tuesday, January 2d, 1894. GEO. TOURNY, Secretary

The Best Mining District On the Pacific Coast GRASS VALLEY, CAL.

THE BEST NEWSPAPER published in the district is THE TIDINGS.

Daily and Weekly edition. Gives all the Mining News. Dealers in Mining Machinery and Mining Supplies will find THE TIDINGS the best medium for directly reaching the owners or managers of mines. Investors in mines will find it to their advantage to subscribe. Many mines are in successful operation, and new enterprises are being instituted and many others are in contemplation. DAILY, \$5.00 a year; WEEKLY, \$2.50, in advance. H. S. SPAULDING, Publisher

PATENT Double-Acting Cornish Plunger.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER. AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, besides doing away with heavy balance bobs often carrying from 25 to 60 tons of balances. Works with 25 per cent less power. First outlay about one-third less. Suitable to any underly or downright shaft. Friction reduced to a minimum. Occupies less space in the shaft. Has been tested about a year and proved to work satisfactory in every respect.

GUARANTEED TO GIVE SATISFACTION.

Special attention is called to this new feature in the drainage of mines and raising water generally, by which a continuous discharge of water is produced on the up stroke and down stroke, instead of on the down stroke only, which is effected by very much less than one-half the weight of machinery now in use.

When the ordinary pump becomes too small for the work it can be replaced by the new one, using the same rod and column, and doubling the discharge of water, a most important advantage in small shafts where there is not room for a larger pump.

Apply to WM NANCE, Grass Valley, Nevada County, Cal.

Adamantine Shoes and Dies

—AND—

CHROME CAST STEEL

Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

THESE CASTINGS ARE EXTENSIVELY USED IN ALL THE MINING STATES and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to above conditions. When ordering send sketch with exact dimensions. Send for Illustrated Circular.

Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y.

H. D. MORRIS, Agent, 220 Fremont St., San Francisco.

Special attention given to the purchase of Mine and Mill supplies.

Metallurgy and Ores.

SELBY SMELTING AND LEAD CO. 416 Montgomery St., San Francisco.

GOLD AND SILVER REFINERY

ASSAY OFFICE.

Highest Prices Paid for Gold, Silver and Lead Ores and Sulphurets.

—MANUFACTURERS OF— BLUESTONE. LEAD PIPE, SHEET LEAD, SHOT, ETC., ETC.

—ALSO MANUFACTURERS OF— Standard Shot - Gun Cartridges,

Under Chamberlin Patent.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

68 & 65 First St., cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoffers, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing the supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.

Agents of the Deaver Fire Clay Co. and for the Morgan Crucible Co., Battersea, England. Also for E. G. Denniston's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

Practical Hydraulics.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

By P. M. RANDALL.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulae, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is especially applicable to the Pacific Coast.

Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated: General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulas Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formula and Rules; Flow of Water through Openings; Weir Coefficients; Triangular Weirs; Flow of Water over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water through Short Tubes and Compound Tubes; Flow of Water through Pipes; Tables of Velocities and Cubic Feet Flow for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend—Circular and Angled; Flow through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.

Price, \$2.00, post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco, Cal.

THE MCGLEW ORE CONCENTRATOR COMPANY.

{ PATENTED }
{ Sept. 19, 1893. }

CHEAPEST, SIMPLEST, MOST DURABLE AND CLOSEST SAVING CONCENTRATOR IN USE.

{ FRANK BARRERE, }
{ Secretary and Manager. }

CAN BE SEEN IN OPERATION AT THE PACIFIC BRANCH UNION IRON WORKS, 127 FIRST STREET, SAN FRANCISCO.....OFFICE, 116 DAVIS STREET

NINETY-FOUR AND ONE-HALF PER CENT

—SAVED—

ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt. SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION. CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE (at present).....\$350 EACH,
Including Prepared Canvas Belt.

FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a True, as after many years experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94 1/2 per cent; from East ledge, * * * a saving of 92 per cent.

The concentrator runs very easy and requires but slight attention. One man attends to rock-breaker, crusher and concentrator.

You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,
E. L. BALLOU, Propr. Ballou Reduction Works.

For the Safety of Miners.

One useful lesson was taught to mine-owners by the late fire at the Idaho-Maryland. Through long immunity from disaster, avenues of escape from mines, in case of accident, have been confined to the main shaft or tunnel. In cases where hoisting works are hurried, very serious consequences might ensue. Fortunately, at the Idaho-Maryland fire, the ventilation shaft, though long unused, was handy, and the ladders were substantial. Many mines are not so well provided. It may not be generally known, but there is a law in this State which requires all mining companies to maintain two shafts after a depth of 300 feet has been attained. Its purpose is to provide means of egress in case escape is shut off in one shaft or the other.

The experience of the Idaho-Maryland miners has awakened others to the lack of alternative shafts, and at the North Star mine, for instance, the Grass Valley Union says Superintendent Abadie has been very active connecting all the hose to the hydrants in case of an emergency. At the present time there is an excellent air shaft through the mine, but repairs are being made that will greatly insure the safety of the miners in case a conflagration similar to the Idaho-Maryland occurs. The air shaft is vertical for a distance of 125 feet and is furnished with wooden ladders. Mr. Abadie states that these are to be replaced by iron ladders which will not be subject to decay. The avenue of escape at the North Star will be made as perfect as experience and ingenuity can suggest, and in case of an accident there will be no cause for worry on the part of relatives or friends.

TRINITY COUNTY, which has heretofore done little to secure representation at the Midwinter Fair, does not propose to be left in the cold. An "Old Settlers" committee, consisting of J. McMurtry, F. M. Paulsen, Geo. E. Noonan and T. E. Jones, has taken the matter in hand and will collect an exhibit. It is designed to show specimens from every paying quartz mine, from placer mines, quarter of an ounce of natural dust, and also samples of copper, cinabar, asbestos, galena, magnetic iron, coal, or any other mineral which can be produced in the county. Besides these, there will be petrifications and relics of past ages.

A NEW SOCIETY is planned for the Northwest, modeled after the American Institute of Mining Engineers. It is estimated that the districts around Spokane contain at least 150 mining engineers, assayers, millmen and real experts who have technical knowledge of mining. It is to increase the knowledge and aid in sifting out the pretenders that the new society is to be formed. Besides the central society, which would hold annual or semi-annual

meetings, district circles would be organized at Helena, Vancouver and other centers. The idea is an excellent one, and it is to be hoped will be carried out successfully. There is no mining organization of any kind in the Pacific Northwest, so far as we know, and the new society would be able to promote the interests and knowledge of the district in substantial shape.

THE gold and silver used in the industrial arts is the subject of a careful calculation in the report of the director of the mint, as in previous reports of the mint bureau. The gold and silver furnished by private refineries during the calendar year 1892 was ascertained by

GREENSTONE OUTCROP ON THE MOTHER LODE.

correspondence with all the firms in the United States known to be engaged in the manufacture of gold and silver bars. The aggregate furnished by both private refineries and the government is given in the following table:

Material.	Gold.	Silver.	Total.
Domestic bullion	\$10,783,703	\$7,204,210	\$17,987,913
U. S. coin	787,334	5,152	792,486
Foreign bullion and coin	771,636	1,249,801	2,021,437
Old material	4,468,685	647,377	5,116,062
Total	\$16,816,408	\$9,106,540	\$25,922,948

There was no material variation in the amount of gold and silver used in the industrial arts during the calendar years 1891 and 1892, the value of gold in 1892 being \$16,616,408, against \$16,644,952 in 1891; of silver, \$9,106,540 (coining value) in 1892, as against \$9,631,746 in 1891. Data relating to the weight and value of bars furnished for use in industry during the fiscal year were received from the government institutions only.

GENERAL A. J. WARNER, President of the National Bimetallic League, has called a convention of the silver men of the country to be held at Des Moines, Iowa, February 22d and 23d. It will be a national convention and the call is issued by authority of the Bimetallic League, under instructions of the conference held last December in Washington.

A Greenstone Outcrop.

The illustration on this page shows a greenstone outcrop in Rancheria creek, Amador county. It is of interest to all miners to know that Dr. Stephen H. Emmens is making some extensive experiments in the greenstone at the Mayflower mine. Those who read his views on the Mother lode, printed in this paper December 30, learned that he took a positive stand against the generally accepted theory on the Mother lode, that development of greenstone veins does not pay. He cites instances where bonanza has been found in greenstone, and feels perfectly certain that he will have no reason to regret prospecting in greenstone in the Mayflower. The result of the Mayflower experiments will be duly given in the PRESS.

MR. CHAS. G. YALE, United States Mint Statistician, estimates that the gold yield of California for 1893 is between \$13,000,000 and \$14,000,000. Mr. Yale's estimate is certainly reasonable. It has been apparent, from the greater activity in gold mining, that the increase would be considerable over 1892, when the yield was \$12,571,000. The list of mines in actual operation was increased during the year. Numerous prospects were turned into mines and many idle mines were reopened. Several important mines have broken their best previous records. In 1892 the largest producer was the Kennedy, in Amador county, which gave up \$443,639.99. It is he-

lieved for 1893 that the greatest producer was the Utica, in Calaveras county, which is said during three months to have yielded \$498,000. The hydraulic mines, except on the Klamath, have as yet added little or nothing to the total output, but the increase will doubtless be considerable in 1894. The average for other minerals in California for 1893 was fairly kept up.

It is reported from Washington that the House Committee on Ways and Means will in all likelihood insert in the Wilson bill a provision taxing crude petroleum. Scrap iron will be on the free list. A determined effort will be made to restore the present duties on borax and quicksilver, with no very flattering prospects of success. California as a whole has perhaps more different important interests directly affected by the Wilson bill than any other State in the Union. California is practically the only State which produces quicksilver. California and Nevada alone produce borax. California is a leading producer of petroleum. With Oregon and Washington, it is practically the only producer of prunes. It is the only producer of raisins. Its fruit interests are widely concerned in other varieties. Its wine interests declare that the hill, if passed, will ruin them. The schedule on wool, lumber, harley and jute goods affects them,

Valley Prejudice Lessening.

It seems a little curious to find so pronounced a valley paper as the Marysville Democrat opposing the proposition to send six delegates to Washington on behalf of river improvement. The Democrat claims that no benefit can result to Yuba county from their mission. But the recommendation of the Government Debris Commissioners for a \$30,000 appropriation to begin construction of a restraining dam at Deguerre point is strongly endorsed. Says the Marysville paper:

The Democrat is clearly of the opinion that this county in particular does not at this time desire a personal representation in the proposed delegation, unless it be to prevent a possible division of the appropriation recommended for the restraining works at Deguerre point. There is where the only danger appears in the proposition of sending men to Washington who are openly hostile to restraining dams, particularly those who have said that there is no merit in them in any place. We now have law and a commission to enforce it and carry out its provisions, and the Democrat has confidence in them and their judgment.

It is pretty well understood that the river improvement delegation will not oppose the appropriation for restraining dams or any other present measure in the interest of restraining dams. The fears of the Democrat are therefore groundless.

It is worthy of note also that the Sutter County Farmer has recently found room for a virtual endorsement of the Debris Commission. Commenting upon the recent action of the Commission in suspending operations temporarily on the Polar Star mine, at Dutch Flat, the Farmer says:

The prompt action of the present Debris Commission in suspending operations at the mine shows that it means business, and will give every mine that has a permit to run careful inspections from time to time. The valley people are expected to assert their rights by keeping thoroughly posted in regard to all these matters, and should not relinquish their careful watch over the vast interests they represent.

One more expression, this from the Colusa Sun, may serve to illustrate further the change of sentiment in the Sacramento valley regarding hydraulic mining:

We have tried not to be a crank on the subject of hydraulic mining. If the people who propose to mine on the tributaries of the Sacramento can take the debris out of the channels and deposit it, we shall be pleased to see them go ahead. No industry, however temporary its effects, shall receive a check at our hands if it does not conflict with interests more lasting.

The old valley prejudice seems to be dying out. It is now realized, perhaps for the first time, that the hydraulic miners desire to comply with a law that conserves the farmers' interests as well as their own.

ANOTHER valuable find out of the common is reported from Florence, Arizona, in the discovery of a ledge of fine black marble, valuable for interior furnishings and monumental work. Some of the marble brought in has been polished. It is handsome, very dark in color and beautifully veined. A body of good granite was also found near.

The New Mining Bill.

The executive committee of the State Miners Association, at its meeting last Friday, decided to urge upon Congress the desirability and justice of material amendment of the present mining laws; and, to that end, to present a substitute for the Stewart mining bill in the shape of the measure framed by a special committee of the association, comprising Messrs. Tiley L. Ford, Chas. G. Yale and Edward A. Balcher. The text of the proposed law was published in the MINING AND SCIENTIFIC PRESS November 12. It embraces the changes recommended by the Miners Association, includes the useful features of the Stewart bill and eliminates others that are obnoxious. It was practically decided to send to Washington one or perhaps two representatives of the association for the purpose of presenting its merits to Congress and urging its adoption. The delegation shall also assist as far as possible in securing passage of the association bill recommending an appropriation of \$1,030,000 for the purpose of constructing government impounding works to restrain mining debris.

The mission of the delegation is most important. It will endeavor to enlist the sympathy and active co-operation of Representatives in Congress from other mining states for the passage of the general bill. This measure was not framed especially in the interest of California, but the design was and is to make its provisions so useful, valuable and comprehensive as to commend themselves to all the mining states. An expression from other States will be solicited and any changes in the present measure that seem in the interest of all will be incorporated. It is therefore probable that the measure as finally presented to Congress will contain new provisions with, perhaps, changes in old. Of course those features particularly recommended by the miners of California will be retained.

The most important features of the bill—the keystone of the arch, so to speak—provide that the presence of rock in place bearing gold, silver, etc., shall be regarded as presumptive evidence that the land is, and always has been, mineral in character; likewise a provision defining how land shall be determined to be more valuable for mineral than agricultural purposes, and providing that this chapter shall be liberally construed by the land department. It is the purpose of these provisions to reverse the policy of the land department, which in its rulings requires that lands, even in mineral belts, shall be actually and severally shown to contain mineral before they shall be adjudged mineral. In other words, the presumption of the land department is that all lands are agricultural or timber until they are finally and conclusively shown to be mineral. In cases of contest between mineral and agricultural claimants the burden of proof is invariably imposed upon the miner, and agricultural claimants have, under this inequitable ruling, been permitted to alienate vast extents of land notoriously mineral from the public domain.

It will be observed, also, that the vexed question of mineral lands in railroad grants has been taken up in this measure, and a practical declaration made in favor of the mineral claimant as against the railroad company. It is well known in California that the Central Pacific company claims all lands within the boundaries of its grant not known to be mineral at the time of filing the map of location of the road. It is supported in its claim by a decision from United States Circuit Judge Sawyer. The provision that rock in place shall be presumed to be and always to have been mineral in character is an effort in the direction of equitable adjustment of the rights of mineral claimants on railroad lands. When Congress excepted mineral lands from the railroad grant, it clearly did not mean to except only that small fraction of the lands at that time known to be mineral.

Other changes in present laws have already been fully set forth in these columns. It will be as much the duty of the Miners' delegation to oppose the Stewart bill, if it is again presented to Congress, as to favor the measure they take with them. They will endeavor to point out its objectionable features to Congressmen and to Congressional committees, and there is good reason to believe they will be able to do effective work.

THE principles of hydraulics were applied with success, Wednesday, to the removal of a great mass of earth which covered the Southern Pacific railroad between Meta and Towles, Calif. Carpenters were sent to the scene, and a large sledge-box was constructed underneath. A stream of water was then turned on, and the mountain-side washed into the gully below. Before this operation was undertaken, however, the tall pines which came sliding down with the earth had to be removed. They had maintained their upright position during the slide. Locomo-

tives were placed on either side of the obstruction, and log chains leading from them fastened to the trunks of the pines. They were then drawn out of the landslide as a dentist draws teeth.

The Future of Borax.

By the Wilson tariff bill it is proposed to place crude borax and horacic acid on the free list, and impose on refined borax an *ad valorem* duty of 20 per cent. The present duty on boracic acid is 5 cents per pound, on crude horax 3 cents per pound, and refined borax 5 cents per pound. The reduction in tariff of the latter is more than one-half—about 65 per cent. The distinction made by the Wilson bill, in its treatment of borax in its various conditions, is not consistent with the general policy of the measure that raw material shall be admitted free and manufactured articles be subject to tariff duty. Refined borax is made to pay duty, and boracic acid comes in free.

No better illustration of the beneficial effect of the tariff on any given industry can be found than in the American history of horax production. Very little of the salt had been produced in this country prior to 1873. Then extensive beds of the borate of lime and soda were found in California and Southern Nevada. Though the material was not high-grade, preparation for its development was made. Foreign dealers and producers became alarmed at a prospective rival, and immense quantities of horate of lime were converted into boracic acid and shipped to New York, being admitted duty free. The effect was disastrous to the American companies. They struggled along for several years, but finally suspended operations altogether. They were unable to compete with the foreign product. Later some of the companies attempted to resume work, but they accomplished comparatively little until Congress came to their relief and placed duties on borax importations. Since then the industry has thrived, with some variations of prosperity and adversity, it is true; but these fluctuations were due as much as anything else to threatened tariff legislation. The failure of the great firm of Wm. T. Coleman & Co., in 1888, was ascribed directly to the tariff agitation, which caused the rupture of negotiations for the sale of their borax properties.

Before the discovery and development of the American horax deposits, the average price per pound of the refined product in New York was over 30 cents. It is now less than 7 cents. The companies are operating on a small margin of profit—if there is any profit. The most rigid economy is practiced in all departments. They are in no position to compete with the cheap foreign product; and removal of the product means, we believe, their material injury, if not their complete destruction. The industry is now one of no mean proportions, the production in 1892 reaching 14,243,099 pounds—greater than for any previous year.

It is difficult to see just what good will come out of the curtailment of the American output and the purchase of borax abroad. The foreign output is, it is asserted, practically under one management, at least so far as shipments to the United States are concerned; and the inevitable effect will be, we think, higher prices than at present prevail if the American competition is paralyzed. It is evident that the home consumers' interests have in the past been conserved by a tariff, inasmuch as the price has fallen steadily and persistently from 39 cents to 7½ in thirty years. The price for the refined product is now just a shade above the tariff. What good purpose will be served if all the restrictions are removed, and the United States draws on the salines of Asia Minor and South America for its supplies?

The welfare of the industry in California and Nevada involves the welfare of a large working force, consisting of laborers in the salines and the attached works, mechanics, woodchoppers, teamsters, etc. The farmers, haymakers and stockraisers in the vicinity of the borate fields would be deprived of a local market for their products—a consequence that would be most disastrous to them. Whole communities are seriously concerned in the matter, as its determination means a great deal for their prosperity.

It is all very well to point out the wide uses to which borax is put, and the resultant advantage to an immense number of industries if cheaper prices prevail. But the claim that cheaper prices will prevail has no sufficient basis; and we feel sure that cheaper prices mean idleness for capital invested in the American industry and the labor dependent upon it.

A NEW FURNACE, designed by Superintendent Rhodes and Metallurgist Klotz, has been added to the Arkansas Valley smelter, at Leadville. It is claimed that every ounce of silver will be saved, none being lost in the slag. The details of the furnace are kept a secret.

What a Buyer Wants to Know.

There are a great many going mines in California which may be bought for a fair price. There are many mines which are not for sale; and there some which are for sale but which will never attract a buyer until more reasonable terms are offered. As a rule, a buyer who knows his business is not willing to risk a large sum on a prospect. He wants a mine, and a hole in the ground is not a mine, though of course it may develop into one. But people in search of mines generally prefer one which has a body of ore in sight, having been developed to a greater or less extent. They want to reduce the chance of failure to a minimum, and, as a rule, they are willing to pay in proportion as additional certainty is secured. Many owners of partly developed claims realize the value of their mines, but they sometimes do not know exactly what a purchaser wants to know. They often think it sufficient to make a few general statements about their property, with the mill returns, when there are any, and the purchaser can find out for himself what he wants to know. Negotiations are often carried on partly by correspondence, and it is, in these instances, desirable that as full, complete, and accurate statements as to the properties be made as it is possible to make.

We have in view a good mine in one of the northern California counties, to which an Eastern man was attracted by favorable report. He examined the mine, and then he made memoranda of the following things which he desired to know and asked the owner to furnish:

1. Make exact map showing cross section and ground plan, giving length of tunnels, shafts, drifts, pay chutes in the workings, width and value of same, whether high or low grade.
2. Give full list of mill results, tons worked and bullion produced, with sworn certificates from mill man, if possible; also specify from what place in the mine such rock was taken; also state whether such rock was sorted, or if all between walls was milled; state character of ore, with principal bases.
3. What buildings, machinery, improvements and tools are now on and go with property.
4. Give profile of surrounding land, showing possible mill site; how water, if any, can be applied; how many inches, and at what head, and whether free or from company ditch; if so, at what price. Can water power be used all winter?
5. Give map of district, showing this mine in relation to others, and give short history of camp, showing production in years past.
6. Give statement as to roads, and access to mine, with distances. If no mill on property, what is distance to custom mill and cost of transportation?
7. Give prices of lumber, lagging, and mining timber and supplies.
8. What is estimated cost of working?
9. Give close measurements of ore stoped out and ore left in mine. Is country rock hard or soft? Give end-view of lode showing ore line and its relation to surrounding surface.
10. What is price of property and terms?
11. What is the nature of title and surface measurement, and extent of claim or claims?
12. What would be the best method of development?

These questions are numerous, but they are all important, and most of them are essential. There are other things in addition which may be stated in a report, and which will add to its value and clearness. Such a statement, embracing the particulars indicated above, can be made by any intelligent miner. It does not involve the employment of technical skill, except, perhaps, in the drawing of the maps. It can be done cheaply, and may lead to satisfactory results. A report on the above lines was largely instrumental in effecting a sale in the case cited above.

Precious Metals in 1893.

The annual statement of the Wells-Fargo Co. relative to precious metal production in the States and territories west of the Missouri river, published in this paper, is full of interest. Comparison with last year's figures will disclose the course of the various metals in a very satisfactory manner. For 1892 and 1893 the statements show:

	1892.	1893.	Decrease.	Increase.
Gold	\$30,119,636	\$34,202,891		\$4,083,055
Silver.....	50,607,601	38,491,521	\$12,116,080	
Copper.....	19,370,516	23,631,339	4,260,823	
Lead.....	11,433,947	7,756,040	3,677,907	
Totals.....	\$111,531,700	\$104,081,591	\$7,450,109	\$8,943,878

The exact effect of the partial suspension of operations in the silver mines is very clearly shown by the above figures. The falling off of silver production has been about 25 per cent; lead, 33 per cent. On the contrary, the production of gold has increased and so has copper. In-

deed, 1893 was the banner year for copper, no previous year having shown such great production.

The production of gold and silver combined in California for these two years is as follows:

	1892.	1893.	Increase.
Gold and silver.....	\$11,593,196	\$13,036,948	\$1,443,752

According to the Mint figures, the production of gold alone in California for 1892 was \$12,571,000. The difference in the estimates is sufficient to indicate that the production for California for 1893, according to the Government estimate, was over \$14,000,000.

Cost to See Midwinter Fair.

The following is printed as a complete list of the concessions at the Midwinter Fair to which extra admission is charged:

	Cen.
General admission.....	50
Hawaiian Cyclorama.....	50
Boone's Arena.....	25
Firth Wheel.....	25
Santa Barbara Sea Lions.....	25
Hawaiian Village.....	25
Dante's Inferno.....	25
Colorado Gold Mine.....	25
Chinese Building.....	25
Chinese Theater.....	25
Moorish Mirror Maze.....	25
Automatic Race Course.....	25
Green's Sculpture Exhibit.....	25
Egyptian Hall.....	25
Oriental Village (gate).....	10
Cairo Street (gate).....	10
Oriental Theater.....	25
Oriental Concert.....	25
Dancing Girls.....	25
Camel Trip.....	25
Donkey Trip.....	10
Haunted Swing.....	25
Heidelberg Castle.....	25
Heidelberg Concert Hall.....	25
Esquimaux Village.....	25
White Cloud Indians.....	25
Arizona Curiosities.....	25
Ostrich Farm.....	25
Forty-nine Mining Camp.....	25
Forty-nine Theater.....	25
Forty-nine Dance House.....	25
Foot's Museum.....	25

Balloon Trip.....	10
Scenic Railroad.....	10
Athletic Grounds.....	25
Mummy Exhibit.....	10
Merry-Go-Round.....	5
Phonograph.....	5
Total.....	\$10.00

"Popular Astronomy."

A new astronomical periodical, under the above title, has recently made its appearance, several numbers of which have already been issued, and the publication gives promise of filling a much needed want in periodical literature. It is designed more especially for amateur students and general readers. It will be issued monthly for \$2.50 per annum, except July and September—ten numbers of 50 pages each constituting a volume. It is "plainly worded, untechnical in language" and amply illustrated. Professors W. W. Payne and C. R. Willard, of Goodsell University, Northfield, Minnesota, are editors. The numbers before us are replete with articles of varied astronomical interest, devoid of technicalities, and so written that they may be readily comprehended by any intelligent reader. We notice among its contributors several prominent astronomers, among whom may be named S. W. Burnham, E. E. Barnard and James E. Keeler, well known in California.

In this connection it is pleasant to note that greatly increased attention is being paid to the science of astronomy, not only in our schools, but by the public at large as well. In many localities classes are being formed, after the manner of Browning, Shakespeare classes, etc., which are found to be much more interesting and profitable to the members. This kind of study is leading to the formation of many amateur astronomical societies, the rapid growth and usefulness of which have been pronounced phenomenal. This study and these associations, in some places, form an important part of the great University extension work which has recently become so popular and useful. The above publication will be found a most valuable aid in such work, and the publishers and editors have kindly volunteered their aid and advice in regard to the formation of such associations, the guidebook which would be most useful and the classification of the work and study which may be required.

The recent application of photography to astronomical work, together with photogravure, has rendered illustration so beautiful and perfect that the amateur can study the heavens almost as readily by such aid as by direct view through the telescope. A little insight into this beautiful study thus obtained almost invariably leads to either personal or associate ownership of the proper instruments, with which original study and research may be undertaken. A very small telescope with the camera oftentimes develops

matters of much scientific value. There is no study which, when once entered upon, so interests and enlarges the mind as that of astronomy.

Sliekens.

The Firth wheel made its initial trip at the Midwinter Fair grounds January 13th. Twenty-three hundred people were carried.

Dr. R. S. HAAVEY, an old pioneer in Washington and Idaho, well known to Conr d'Alene miners, recently died a Spokane from the effects of a fall.

The town of Mullan, Idaho, narrowly escaped being carried away in a snowslide last week. Several miners' cabins were crushed, and Cornelius McVey and John Lyon killed.

The production of the Delamar, Idaho, mines for December shows an increase over the average report. Manager Plummer shows a gross production of \$92,212, an estimated profit of \$52,547.

GARAT activity has recently marked the working of the Anacoda (Mont.) copper properties. It was recently estimated that by Jan. 15th 1800 men would be at work. Three weeks ago the total number was 300.

The Nance double-acting plunger Cornish pump was last week by error referred to as having been tested for a year at Grass Valley. The test was made at the Hontington Copper and Sulphur Company's mines, Wellington, near Magogg, Canada.

It is stated that there are now in the United States more than 300 mining companies making use in their operations of electricity for light and power. About one-third of the gross amount of copper refined in this country is now treated by electrolytic processes.

The Golden Star Mining Company has incorporated with a capital of \$100,000, of which \$10,000 has been actually subscribed. Principal place of business, San Francisco. Directors—James McCormick, William M. Pereira, F. P. Otis, George W. Grayson, A. M. Silverstein.

The Needles Reduction Works will soon be running once more. Messrs. Sheridan & Fairfield are simply awaiting the arrival of some heavy belting which had to be ordered from New York, and which will be here the coming week. As soon as it is received, the mill will be prepared to handle ores.

The directors of the Idaho Mining Company, Grass Valley, have declared dividend No. 279 of \$8 per share, aggregating \$18,600. They also voted to appropriate \$100 to the mineral exhibit of the Midwinter Fair. Fifty dollars of this goes toward the Nevada county exhibit and \$50 to the general State exhibit.

At the annual meeting of the Brunswick Con. Gold Mining Company the following officers were elected for the ensuing year: J. B. Robinson, president; J. J. Harpin, vice-president; T. H. Chandler, W. H. Philbrook, W. C. Wallace, directors; H. R. Lonsberry, general manager and treasurer; J. Stadfeldt, Jr., secretary; W. A. Hawley, superintendent.

The total product of the Kaslo-Slocan mines for the year 1893 in round numbers was 2462 tons that will average, at the present price of silver and lead, \$165 to the ton, or a total output of \$406,230 worth. The Kaslo-Slocan Examiner estimates that 5000 tons will be shipped from the Slocan country to the smelters of the United States during the present season.

A SMALL SENSATION has been sprung in the Northwest by the discovery that there is in file in Washington a petition favoring free lead ore, forwarded by the Conr d'Alene Miners' Union. It has been explained that the petition was gotten up last year during the Conr d'Alene troubles as a means of retaliation upon the mine-owners. Efforts are now being made to secure withdrawal of the petition.

At the annual meeting of the stockholders of the St. John Quartz Mining Company, Nevada county, the following were elected as a board of directors: D. E. Matteson, W. J. Michell, Lewis Wheeler, Wm. Treloar, John Aver, of Grass Valley; A. G. Huggins of San Jose; W. L. Thompson of Orland. The board organized by electing D. E. Matteson, president; W. J. Michell, vice-president; Lewis Wheeler, superintendent; J. M. Wiley, secretary.

The hotel at De Lamar, Idaho, burned recently, and the firemen, seeing the fight hopeless, devoted themselves to saving the office of the De Lamar Mining Company. Capt. De Lamar arrived on the scene and, noticing the firemen at work, roared in a voice of thunder: "To hell with the office! See that the poor families up the street do not lose their homes!" It is gratifying to know that the homes of the poor were saved, and that the office did not make the journey so unprofitably recommended by the captain.

"JIM" WARDNEA writes from Johannesburg, South Africa, to the Spokane Review: "I do not advise any man to come here who is not well equipped with experience and money. The country is full of Cornish miners and more coming. Nearly all the Australian miners have left that could go. But to the man—the American man—with \$5,000 to \$10,000, this is the place. Skilled men of many classes are in good demand, such as electricians, workers in wood and iron, carpenters and stonemasons. The wages are universally £1 sterling per day."

THERE is work enough on hand at the Tacoma smelter to keep the full force employed steadily till the 1st of February 1895. Manager W. R. Rust tells the Ledger that he has just closed a deal for the purchase of 7500 tons of gold ore from the Conster mine in Montana. The purchase price is \$400,000, of which \$30,000 is to be paid monthly. Manager Rust said also that the smelter is prospering, even during the general stagnation. Since the depression began it had paid off a debt of \$130,000, and was now entirely free from incumbrance. He proposes to put in next spring two more roasters, thus doubling the capacity of the plant.

Foundry Notes.

A GRIFFIN mill of 40 tons capacity is to be placed at the Mammoth mine, Arizona.

The offices of the California Wire Works have been removed to 509-511 Market street, San Francisco.

Mines and Mining in Nevada County.

From Our Regular Correspondent.

During the conflagration which occurred at the Idaho mine on Tuesday of last week, and while the smoke from the dying embers was slowly wafted skyward, men looked at each other askance and asked the question: What will be the result? Will they rebuild? These questions were repeated so loud and often that they echoed and re-echoed through my mind, and I even had the credulity to repeat to myself the question: Will they rebuild? The extreme absurdity of such a puerile question must be apparent to every one acquainted with the Idaho-Maryland property and its management. The fact that the Idaho has produced \$12,000,000 in gold bullion, one-half of which has been divided among the fortunate stockholders, and the further fact that since the transfer of the Idaho property to the Maryland company, which occurred less than nine months ago, over \$70,000 of the purchase price has been paid, should convince the most obtuse that work would be resumed immediately. It should be remembered by those unacquainted with the facts that the money paid to the Idaho company has been extracted from the Maryland mine through the Idaho workings. In face of these facts, does it not seem ridiculous to ask the question: Will they resume operations? The Maryland mine is great in extent and wealth. The compromise which was effected some months ago, after long and costly litigation, and through which the Maryland company became the possessors of the Idaho property, was accomplished with a view to promote the best interests of this community. And from present indications there is every reason to believe that the Maryland mine will be as rich and famous as its illustrious predecessor.

It is very gratifying to know that active operations have been resumed on this property, and that within a few weeks, every condition being favorable, the full complement of men will be employed. The throwing out of employment of 200 men, even though it be only temporary, must necessarily exercise a depressing influence in any community. The city is losing \$600 daily in wages alone, not mentioning the other multifarious expenses of such a large mine. But this will soon be regarded as past history by our residents, and we look forward to a bright and successful future for the Maryland mine.

In this misfortune Mr. S. P. Dorsey, president of the Maryland company, has the sympathy of the entire mining community of this county. Mr. Dorsey is a gentleman of great energy and enterprise, qualifications which make him a useful and valuable citizen. He has stood by the Maryland mine throughout its chequered career. All his wealth has been invested in the development of this property. Costly litigation almost impoverished him and prevented him from properly developing his property; and when his efforts and endurance were about to be crowned with success, when the consummation of his desires was almost accomplished, this disaster befell him. But Mr. Dorsey will succeed in spite of this serious impediment, and will yet become the possessor of great wealth.

The Idaho disaster has had one good effect—it has spurred the mine managers of the district to greater precaution in protecting the lives of their employees. They have also made extensive preparations for the protection of property in case of a similar conflagration. While the fire was raging at the Idaho mine, the greatest anxiety was manifested by the spectators regarding the safety of the miners. For a time there was some doubt as to the condition of the air shaft through which egress must be made in time of fire. But the men escaped through this avenue without accident of any kind. Every large and well-regulated mine, and smaller mines as well, should provide proper means of egress for those who labor in the subterranean depths. Delinquency in this respect should be punished by criminal proceedings. Only men of the most indifferent and dilatory character will disregard the interests of their employes in such a manner. I am pleased to state that greater precaution is being exercised by our mine managers, and that extensive preparations are being made to protect life and property in case of an emergency. Especially is this so at the North Star mine, where Superintendent Abadie has had hose connected to every hydrant. He is also making preparations to have the wooden ladders, with which the air shaft is now furnished, removed, and to replace them with iron ones. These will not be subject to decay like the wooden ones.

Last week an injunction was placed upon the Champion mine of Nevada City by the Wyoming company, and operations were immediately suspended. It is contended by the latter company that the Champion company have been making encroachments on their ground, hence the suit. The closing of the Champion mine in this manner will naturally affect the activity of Nevada City. This

mine is one of the largest and most prosperous in Nevada county, and the suspension of operations is greatly regretted. Litigation between mining companies is always costly and tedious, and it is to be hoped that this matter will be amicably adjusted without reaching the courts.

With the exception of the Idaho catastrophe, mining in this district pursues the even tenor of its way. The prospects for quartz mining were never brighter than at the present time. Increased interest is manifested by outside capitalists, and we predict for the year 1894 an era of unprecedented prosperity. We hope to see the rehabilitation of several abandoned mines whose wealth has never been questioned. There are millions of untold wealth lying hidden in these caverns, which only await the application of science and capital to extract it and permit it to circulate through the veins and arteries of the commercial world. These mines, with which our hills are dotted, have been abandoned because of the great expense incurred in developing them on account of the immense bodies of water encountered in the course of working. A large number of these undeveloped mines were abandoned in the early days, when the facilities for their development were not so great as they are to-day. As gold producers they possessed a national fame. They produced in the aggregate several millions of dollars, and there is every reason to suppose that when rehabilitated they will greatly add to our present production. There are plenty of precedents for this conjecture. Every one of our deep mines, with the exception of the Idaho, has at some time in its history been abandoned for the same causes which have led to the abandonment of the mines which to-day lie idle and undeveloped in this county.

Several carloads of gold-bearing quartz have been sent to the Midwinter Exposition from this county for use in the mill erected on the grounds. Nevada county is the Nestor of quartz mining. And we propose to show the visitors to the Fair that we have the richest gold-bearing ledges in the world. The mineral thus sent has been impartially selected by the managers of the different mines. No attempt has been made to create a false impression regarding the richness and extent of our mines. We are content to have the visitors judge the greatness of our mines upon their merits alone.

Great benefit must necessarily accrue to this county through the medium of having the quality of our ores tested by such process. I understand that when a "clean-up" is made the result will be duly announced, with the name of the mine from which the ore was extracted, the amount of ore crushed, the total yield per ton, etc. I hope this method will be adopted and strictly adhered to.

The managers of the Electric mine, formerly known as the Green Mountain, have purchased a mill and will shortly transport it to their property. The mill consists of 20 stamps, with concentrators and all the appurtenances of a first-class mill. It is pleasing to note the rapid developments that are occurring at this mine. Some months ago it was reopened by Mr. Dan Coffin, who is the principal owner, and under his management rapid progress has been made in development. Several crushings have been extracted that have yielded immensely; in fact, so productive in gold is the quartz in this mine that the results of the crushing have always been kept a secret. We regard the Electric as one of our future gold-producers.

Operations at the Hudson Bay mine have been resumed, after having been suspended for some months. Superintendent Tregidgo asserts that the mine will be developed as rapidly as circumstances will permit. He has been rather unfortunate with this mine, having had to suspend work on several different occasions. But we hope that as soon as the shaft is relieved of its water, work will be continued without interruption and the mine will quickly become a regular dividend-payer. The mine is in a good locality, adjoining the famous new Rocky Bar mine, and has a course on the vein of 1600 feet. The manager, Alf Tregidgo, is one of the best known mining men in California. He is an indefatigable prospector, full of energy and enterprise, and is greatly deserving of success. He has invested much capital in the mines of this county, and it is the unanimous wish of all that his enterprise will be crowned with success.

Last week the Debris Commissioners, in company with State Commissioner Kidder, visited the Hustler, Kate Hayes and Manzanita mines on the San Juan ridge. The object of their visit was to inspect some of the mines which had made application for a license to resume operations under the Caminetti Act. We could not learn the conclusions arrived at by the Commissioners as a result of their visit, but we are convinced that for every application made a license will be granted, after all the requirements of the law have been complied with. SAMUEL BUTLER, JR.

Grass Valley, Jan 17, 1894.

Precious Metals in 1893.

The annual report of John J. Valentine, president of Wells, Fargo & Co., shows that precious metals produced in 1893 in the States and Territories west of the Missouri river (including British Columbia) were as follows: Gold, \$34,202,601; silver, \$38,491,521; copper, \$23,631,339; lead, \$7,756,040; total gross result, \$104,081,591. The "commercial" value at which the several metals named herein have been estimated is: Silver, 74 cents per oz.; copper, 10 cents per lb., and lead, \$3.50 per cwt.

Mr. Valentine says by way of explanation: "As in former reports allowance must be made for probable variations from exact figures, by reason of constantly increasing facilities for transporting bullion, ores and base metals from the mines outside of the express and the difficulty of getting entirely reliable data from private sources. Estimates obtained in this way are liable to be exaggerated and are, to a considerable degree, guess work; but with some modifications on this account, made herein, the general results reached, while only approximately correct, may be accepted as the closest approximation possible under the circumstances."

STATES AND TERRITORIES.	Gold Dust & Bullion by Express.	Gold Dust & Bullion by other Conveyances.	Silver Bullion by Express.	Ores & Base Bullion by Freight.	Total.
California	\$ 9,697,036	\$1,475,000	\$ 557,005	\$1,667,907	\$13,096,048

Hydraulic Mining.*

A REVIEW OF THE INDUSTRY BY DR. HENRY DEGROOT.

In Eight Parts—Part IV.

Dams and Reservoirs.—For arresting and diverting the water of the supplying stream into the ditch, a dam of some kind will be required. As the mountain rivers and streams of California are torrential and subject to violent floods, these structures need to be solidly built. They are usually of two kinds, one being constructed of round or hewn logs so placed across each other as to form a series of cribs from eight to ten feet square, these logs being notched so as to lock into each other and fastened together with wooden pins, or, better, with iron bolts, the bottom timbers being bolted to the bedrock.

As the dam is built up these cribs are filled with rock. To render it tight the face of the dam is planked, the seams between the planks being fattened or calked. A cheaper and more common style of dam is made by felling large pine trees across the stream and then placing the butts of other and smaller trees on these with tops up stream. This

California, and the consequent low stage of water in the larger streams, some of which fail altogether, the storage of enough water to enable the hydraulic miner to continue or much prolong his operations during this, the most favorable season for the same, becomes to him a matter of paramount importance; hence the construction of the many large reservoirs found in the mountains of California, formerly drawn upon to supply the hydraulic ditches when the running streams failed.

Hardly anywhere else in the world can be found such costly and capacious reservoirs as these in the region above indicated, although similar structures, designed to fill the irrigating ditches, are now being built in other parts of the State, some of which, as regards cost and holding capacity, rival the great water repositories cradled in the basins high on the western slopes of the Sierra Nevadas.

These stupendous works were projected and built at a time when the hydraulic miners had reason to believe that they would be permitted to carry on their operations without interruption—at a time when the people and the public authorities of this State were applauding the enterprise of

same formation as the bedrock—the floor of the channel. Not in all hydraulic deposits, nor perhaps in a majority of them the world over, does the bedrock tunnel become a necessity. In California these adits are not much needed except along the central portions of the main gold belts, the sites of the dead rivers or ancient pliocene channels. Elsewhere in the State these deposits occupy, for the most part, the channels of more recent streams, being the former beds of the present rivers, which, on becoming filled up, were deflected from their courses. Owing to frequent shiftings, or other causes, nowhere have these streams eroded the deep, rocky troughs characteristic of the dead rivers. The extreme richness of the latter, many portions of which contain enough gold to warrant their being exploited by the drift method, more than compensates for the additional cost necessitated by the driving of these tunnels.

Where a tunnel of this kind requires to be run, a shaft should first be put down to bedrock in order to determine the level on which it is to be carried. In, otherwise there is danger of its being too high, thereby defeating the end it

MIDWINTER FAIR—MAIN ENTRANCE AGRICULTURAL BUILDING. (From Photograph Taken, Dec. 10, 1893.)

done, another layer of trees is placed on at right angles to the last, this process being continued till the structure is raised to the proper height. Each layer of trees as put down is covered with rock, gravel and brush, forming a mass not easily affected by the greatest floods.

Hardly ever are dams of masonry or framed timbers built for filling these ditches, as these other and cheaper structures generally answer every purpose. Sometimes nothing more than large boulders are thrown into the stream, these serving to divert enough water to fill the miner's ditch.

For regulating the admission of water into the ditch a gate must be placed at its head, the drop in the gate being raised and lowered by means of a lever or screw. Where practicable it is well to have the upper part of the ditch, for a few yards at least, cut in solid rock, as affording greater security to the gate and the ditch itself against floods.

Owing to the occurrence of the long, dry summers in

the builders and encouraging them to make these heavy expenditures.

That this outlay should have proved disappointing and fruitless was not the fault of the men by whom it was made; and although these works, now practically wrested from the owners, may not be permitted to subserve their original purpose, they will not always remain as at present, profitless and useless. They will, in the hereafter, be made to promote other industries and interests, to the advantage of parties other than those to whose energy and trust they are indebted for their existence; but, even then, their founders remaining despoiled and unrewarded, these works will stand forever on the mountains overlooking all California, a monument of our engineering—a reminder of a flagrant judicial wrong and a great national injustice. Having been so eliminated from the business of hydraulic mining, no detailed description of these once important adjuncts of that industry need be given in this paper.†

Bedrock Tunnels.—The bedrock tunnel, so called, is an adit driven to reach and open up the gold-bearing gravel deposit where this rests in a channel having rocky sides, the latter termed often the "rim-rock," it consisting of the

is designed to subserve. If the tunnel on reaching its objective point is found to be too low, a shaft must be raised connecting its inner extremity with the washing pit. Through this shaft the water and gravel is dropped into the tunnel, and by it transmitted to the sluice set below its mouth, the tunnel itself usually being paved throughout its entire length with cobbles or wooden blocks. As these tunnels are so little needed outside of the enjoin districts of California, now idle and in which but few additional structures of this kind will ever be required, a more minute account of them is hardly necessary here. Their character as regards size, grade, etc., will naturally suggest itself to the builders, the rule being to adapt the size of the tunnel to the work to be done, and give it all the grade there is to spare. Frequently it happens, even in these pliocene formations, that large bodies of gravel stand above the rim-rock. Where such is the case, washing may be commenced and carried on for a long period, the construction of the bedrock tunnel being meantime delayed.

ONE more life has been lost in the search for the fabled Pegleg mine, on the Colorado desert. S. W. Pratt, a San Francisco millwright, who has devoted much time to the search, has not been heard from for many months, and has undoubtedly perished. There is no reasonable doubt that

*This article was prepared by the late Dr. De Groot for the Eleventh Report of the State Mineralogist, just issued; but its publication with that of much other valuable matter was prevented by the necessity of revision and omission, so that the volume might be reduced to reasonable limits. It covers familiar ground, but is, on the whole, a complete and careful review of the industry and hydraulic-mining methods. The article has been furnished this paper by State Mineralogist J. J. Crawford.

†It may be well to say that these works now bid fair to be used again to a considerable extent in hydraulic mining. Many of them also supply water for power in quartz mines.

the Pegleg is a myth, and that the hunt for it will always be useless. Last year ex-Sheriff Aguirre, of Los Angeles, and a party of three, after incredible hardship, found the land-marks indicated by old Pegleg, and hunted faithfully for some days for the ledge or the nuggets which Pegleg declared abounded there. They consider it impossible that the gold could have escaped their search, and returned convinced that Pegleg was a dreamer—or, as they somewhat inelegantly expressed it, “a blamed old liar.” The experience of this party, which reached the locality, and of others which have perished, ought to deter others from the useless quest.

A New Mineral.

The Australian Broken Hill Consols mine is well known as yielding a greater variety of ores than any other mine on the barrier, says the Broken Hill (Australia) *Age*. To give a complete list of what has there been unearthed would require more space in these columns than we have to spare. Not long ago we drew attention to the fact that sternbergite had been met with—a mineral that is rare all the world over—and which, as far as we can ascertain, has not before been met with in Australia. The one to which attention is now directed is new to science, and at the suggestion of Mr. Pittman, the Government geologist, has been named “willyamite.” It contains antimony, cobalt, nickel and sulphur, and traces of iron, copper and lead. Its discovery is due to the great interest taken by Mr. George Smith, of the Consols mine, in all matters relating to mineralogy. It is not necessary at this time to say more than this, because Mr. Smith's ability in determining minerals is known in many places outside of Broken Hill. After determining the mineral, Mr. Smith sent a description and samples of it to Mr. Pittman, and that gentleman very kindly undertook to bring the discovery before the Royal Society of New South Wales. To this end he prepared and read a paper before the society last week.

A remarkable feature in connection with willyamite is that it was found in one small patch only associated with a one-half cwt. lump of dyscrasite (antimonial silver); and, although several lumps of the latter were found in close proximity, only one contained the new mineral. Strangely enough, a similar piece of dyscrasite from the same locality was found to contain the rare mineral sternbergite, and it was only with this one piece of silver that sternbergite has been discovered in the mine, an interesting coincidence, seeing that both these lumps of silver were so closely connected *in situ*. Complete analyses have been made by the Mines Department, and the composition was found to be as follows: Antimony, 56.71; cobalt, 13.84; nickel, 13.44; iron, trace; copper, minute trace; lead, trace; sulphur, 15.92; total, 99.91, agreeing very closely to the formula $\text{Co}_2\text{S}_2, \text{Ni}_2\text{S}_2, \text{CoSb}_2, \text{NiSb}_2$. Willyamite crystallizes in the isometric system, possessing the perfect cubical cleavage characteristic of analogous minerals; its specific gravity was found to be 6.8 and hardness about .5. Cobalt has been for some years of common occurrence at the Consols mine in the minerals cobaltite and erytherite, but to the best of our knowledge the discovery of nickel has not hitherto been made at Broken Hill. This is the second occasion, at least, on which Broken Hill has given a new mineral to science, *i. e.*, marshite and willyamite. The fact says much for the ability of the discoverers, and Australia should be proud of them.

Free Lumber.

The Puget Sound *Lumberman* says: “How free lumber will effect the Pacific Coast can be easily figured out. The capital invested in the lumber industry in Washington, Oregon and California is not far from \$50,000,000; nearly 27,000 are paid in wages \$18,000,000 annually. Washington and Oregon last year produced 1,700,000,000 feet of lumber. Of this amount 350,000,000 feet were shipped to California and about 300,000,000 feet were shipped to foreign ports and the East. At the same time nearly 2,000,000,000 shingles were cut in the two States, over one-half of which found markets in the Eastern States. The industry brought into the two States about \$12,000,000 last year, and is consequently the mainstay of the Pacific Northwest. This trade is threatened by British Columbia and Canada in the event of the Wilson bill becoming a law. Lumber carried from Washington and Oregon to any port within the United States must be carried in American bottoms. This places the Washington and Oregon lumbermen at a disadvantage in case of competition with British Columbia, and the California market, which takes fully one-half of the exports of lumber from Washington and Oregon, will practically be given over to British Columbia if the Wilson bill becomes a law. In the Eastern markets the influx of Canadian lumber can be depended on to retard the introduction of Washington and Oregon lumber, and the shingle industry will suffer also from the same cause.”

A Decision in Water Rights.

The State Supreme Court, in bank, has handed down a decision in the case of the Natoma Water and Mining Company, respondent, *vs.* Hancock *et al.*, appellants, on appeal from Sacramento county.

In an opinion written by Chief Justice Beatty, and concurred in by Justices Harrison and Fitzgerald, the judgment and order of the Superior Court are reversed and the cause remanded for a new trial. Justice McFarland dissented *in toto*, and adhered to his former opinion in Department. In a separate opinion, Justices Patterson and Garoutte concurred in the reversal of the judgment. Justice DeHaven rendered an opinion, dissenting from the judgment.

The case decided was an action to enjoin the appellants from diverting water from the South Fork of the American river, at a point immediately above the dam of the respondent, and the principal question involved in the case is as follows: If a prior appropriator of water constructs a dam across the bed of a stream for the purpose of raising its surface at a level which will cause it to flow into his ditch, does he thereby acquire such an exclusive right in the bed and banks of the stream, as far as the slack water extends above his dam, that he can enjoin a subsequent appropriator of the surplus from tapping the stream and diverting such surplus at any point above the dam and below the head of the slack water?

The decree of the Superior Court, from which the defendants appealed, cannot be sustained without affirming this proposition. The plaintiff has at all times diverted water to the full capacity of its canal, and applied the whole of it to beneficial uses, for mining and irrigation. It still requires for irrigation and other useful purposes all the water so diverted, and as against a subsequent appropriation has an undoubted right to continue such diversion unmolested and undisturbed, except in so far as a lawful appropriation and diversion of the surplus at a point above its works may involve the necessity of altering and perfecting the appliances which have thus far proved sufficient to fill its ditch.

If, when on re-trial of the cause the rights of the parties under the contract are again submitted for decision and regulation, the Court should find the extent to which the plaintiff's canal was enlarged in 1862, and, precisely and definitely, the dimensions and setting of the box which the defendants and their predecessors put in and used, in pursuance of plaintiff's grant.

Rough Experiences in Australia.

The great drawback in the new Coolgardie fields in Australia is lack of water. The sufferings of a party are thus described in an Australian paper:

Some ten weeks ago a Mr. Besant, of Newcastle (N. S. W.), with his son Walter, a man about 30 years of age, proceeded to West Australia with the object of getting work at Coolgardie. Leaving Perth, the men unfortunately took the wrong route; but after meeting with many hardships reached the field and took up a claim in conjunction with several other miners. They found a good deal of the precious metal, but discovered that water was terribly scarce. The gold was so very fine that a supply of water was found to be absolutely necessary for its treatment, and their venture was, therefore, only partially successful. Mr. Besant went to work in Bayley's Reward claim, and the young man, with 17 others, struck out for a new diggings 90 miles distant. In a letter to his mother Walter Besant gives a graphic account of the sufferings which befel the party. They took, he says, as much water as could be conveniently carried, but the supply was far too small for their journey. To add to the horrors of their situation they lost their way in the wilds they had to traverse, and were reduced to such a condition that the daily allowance of water was only two teaspoonfuls per man. The pangs of thirst became intense, and the ordeal was made the more terrible by the great heat. In this dire extremity young Besant determined to return to Coolgardie for assistance, and commenced his solitary journey without delay. He had to travel a distance of 130 miles through an almost trackless waste and in a very exhausted condition. Before reaching the end of his journey he met a party of miners also bound to the gold field. He explained the condition in which he had left his companions, and begged the strangers to return to their assistance. His request was refused, however, and he was compelled to plod on to his destination. Upon arriving at Coolgardie he related his sad story, and measures for supplying relief were instantly adopted. Camels, provisions and water were procured, and he acted as guide to the succoring band. The other members of the party were eventually reached, and were found to be in a frightful state. Two men were lying dead, and five others were on the verge of insanity from the effects of their awful sufferings. Some of the men had

torn off their clothing in their delirium, and were perfectly naked, and others were at their last gasp. The survivors were brought round gradually, and were then conveyed to Coolgardie. Young Besant is still at Coolgardie, and states that it is the richest field he has ever seen, but has a great drawback in the scarcity of water.

Gravel Channels of Plumas County.

Abridged from Article by E. C. H. in Plumas *National Bulletin*.

Gravel mining in this county is comparatively an undeveloped industry. The same may be said of quartz. While it is true that gravel has been worked since the earliest days, yet when the vast group of ancient river-beds, a majority of which are still undisturbed, are considered, it is at once apparent that this special branch of mining is as yet scarcely begun.

For the practical miner, or the capitalist, who may invest a portion of his wealth in opening these channels, it is sufficient to know that they exist, and where developed the investment will yield many fold. The old channel system, especially in this vicinity, is an extensive one. Within a radius of a dozen miles fully that number of clearly defined channels are found. A few are intact for many miles in extent. Others are more or less broken from convulsions and erosions. Those lying low have, in the past, been worked extensively by hydraulicking and yielded vast amounts of gold. It is hoped that they will be worked to the fullest capacity in the future. The larger and more extensive channels, which are generally situated on the higher elevations, ridges and divides, seem the more favored locations, and being higher than the surrounding country, and with precipitous sides, afford excellent sites for tunnels. It seems to the observing mind strange that, with all the natural advantages at hand that man could reasonably wish, these river-beds have not long since been explored; but they have not, and no one, not even the privileged citizen with whom the country is burdened, can say there are no mines in these channels, for as yet not one of them has been opened, all owing to the fact that the resources of Plumas are unknown outside its limits. A few attempts have been made by so-called rich companies, both foreign and Eastern, but with disastrous results. These companies were formed in the East and in foreign countries, of Eastern and foreign capitalists, headed by adventurers with far more cheek than practical knowledge. A corps of officers, Eastern or foreign, were also sent, whose combined knowledge of mines, when simmered down, would not equal that of a Chinaman, and the number of officers sometimes outnumbered the working men.

Thus the money was squandered, while development work remained a secondary consideration. It requires only a limited number of men to run a tunnel, with a practical miner as foreman. If the money that has been thrown away by adventurous persons and that paid to high salaried officers had been judiciously spent, many paying mines would be in operation here to-day. The advent of such a company in a mining section is generally hailed with delight by the people, because times are made better, but it were far better for the section if such companies had stayed away, for when the reaction comes, as it invariably does, times are left in far worse condition than before; besides, the country gets what is called a “black eye”—a set-back from which it takes a long time to recover.

There is plenty of room for legitimate enterprise in Plumas county. I honestly believe and assert, that no county in the State can offer as promising a field for capitalists and prospectors, for lucrative investments. The surface “diggings” have yielded immensely. The sources from which spring this yield lie invitingly open, awaiting intelligence, energy and capital to bring forth their hidden treasures. It is often stated that the county is unprospected. This is a literal fact. Every rich surface deposit has its feeder. These feeders remain, the most of them, undiscovered.

What the country needs greatly is a small army of prospectors that know how to trace a lead. Such men will find fine opportunities in this section. Our mineral exhibit has undoubtedly awakened widespread interest in the county. We hear and see evidence of it every day, and the longer the exhibit is kept before the public, the greater will be the benefits.

The coming season is going to be the liveliest that the county has seen for many years. Already several large enterprises have been started, and many thousands of dollars have been circulated in our midst. The enterprises spoken of are strictly legitimate, and here to stay. When such well-known and successful miners as James O'Brien and O. B. Campbell pass judgment on the mines of Plumas and call them good, and back their judgment by buying the largest hydraulic mines in the county, it is a great recommendation. And these men have taken millions from the mines of Yuba and Nevada counties, where the largest mines of the State are situated.

Why the Golden Feather Brought No Returns.

The fourth ordinary stockholders' meeting of the Golden Feather Channel Co. (Ltd.) was held in London, December 21, 1893. The chairman, J. T. P. Pechey, presided. In addressing the stockholders, he said: "Gentlemen, I am quite sure you have all read and very carefully considered the report and accounts, which, on behalf of your directors, I now ask you to adopt. You have also studied the report of our general manager, Col. McLaughlin, and you have been able to form a pretty accurate conclusion as to the reasons which have prevented our obtaining returns during the season which has just closed. If this be so, I am sure that you cannot have failed to understand that the failure to obtain returns this season is due to circumstances over which there could be no possible control. [Hear, hear.] All the same it has been a very great disappointment to us—perhaps to the directors even more than to you—because, gentlemen, we have not only all the responsibility and all the anxiety on our shoulders, but we have also to stand the brunt of the continuous fire of criticism—generally childish and all of it spiteful—which has been assailing this company from its inception. [Hear, hear.] But though we are disappointed, I am glad to say that we are not in the slightest degree discouraged. [Hear, hear.] We have a most arduous task in this company—to fight a continuous battle against all forces of nature. As we tell you in our report, all the natural difficulties of working a river-bed in a mountainous district constitute the chiefly speculative character of this enterprise. Now, let me go back to the cause which has prevented our getting returns this season, and I must ask you to carry your memories back to the big storm of November, 1892. That storm raised the Feather river to a higher point than had ever been known for 13 years. The Feather river in 48 hours was raised 40 or 50 feet above its natural level, and, instead of running along a width of 100 feet it spread itself over half a mile. You can well understand that although our head dam and our canal and permanent works passed through the ordeal almost without injury, yet, still, all the "running tackle" was carried away. The river came down in such tremendous force that the debris filled up the ground which had been opened out last year, 400 feet, which was worked out during the season 1892. That would not have mattered if the timbers had not come down with such force that they broke up the lower part of the elevator. Consequently, when the debris came down and filled up this pit, and when work had to be recommenced at the beginning of this year, instead of our manager being able to turn on the water and at once deal with the debris, he had to sink through an enormous mass of debris and broken timbers until he could reach the elevator and set it going. There are just three points which have delayed us this year—first, the delay which was caused by the very late season, in consequence of which we did not get to work for something like five weeks later than last year; then there was the breaking up of the elevator, and having to sink through all this mass of debris and timber before it could be set to work; and, lastly, there was a mass of debris in the pit which had to be cleared before the manager could attempt to do the work he was preparing to do before the storm burst—that was the construction of a new and perfectly tight foot dam. He had been very much handicapped by not having a proper foot dam. The one we have been working with hitherto was not fixed with its foundations in the bedrock, but simply on the debris which overlay that bedrock; consequently the moment the claim was pumped out and the pressure of the water came from the river there was continuous seepage going on, and that seepage took nearly half the power of the elevators to contend with. I am glad to think that that will not be so in the future. Now, all this does not in the least affect the value of the mine. We know by our experience of the last two seasons that we can get to the bottom of this river, and that in favorable seasons we can work to the bedrock, and we also have been told from time to time that there is gold in the bottom of this river-bed. Perhaps you are almost tired of hearing that story, but we have such positive evidence on the subject that any business man carefully weighing it cannot come to any other conclusion than that we have in front of us a very rich deposit of gravel indeed. First, there are the old records still existing in Oroville, which tell us of the large amount taken out of the Cape Union claim in the early days. Then we have the testimony of those men who worked on the Cape and Cape Union claims, in futile attempts to sink and dredge out the gravel by means of iron pipes and all sorts of appliances. I happen to have received a call the other day from a gentleman who was in Oroville, interested in this suction effort at the time the trial was made. His evidence only goes to corroborate what we have told you—that there is an enormous amount of very rich gravel left by the Cape Union claim-owners when driven out of the early workings. If that is not suffi-

cient evidence, then we have the evidence of Mr. Borwick and Mr. Kirkpatrick and others who have seen the property. We know what Mr. Borwick washed out a few hundred feet ahead of the elevator, and with that evidence before us our faith remains unchanged. It is simply overwhelming as to the results we may look forward to obtain when we can once get to work upon this gravel lying before us. I am not one to come and tell you this if I thought there were any likelihood of this effort being a failure. I do not believe in throwing good money after bad, and if we had worked out 2000 or 3000 feet of the 8000 feet of river-bed that we own, and had then found that the gold was not there, I should say to you at once, "throw up the sponge," but it is nothing of the kind. We have worked only 400 feet, and that in a portion of the river-bed where we now know it was impossible to find returns. We have been terribly handicapped by the lateness of the season and various other causes, but I am thankful to think that we do stand in a different position to-day as regards next season—in a better position than ever before. [Cheers.] We are determined, as long as we believe in this thing, to carry it through, and you are going to help us. Pardon a little digression.

"When I was in California there was a great gold excitement that took place in a part of the United States called Pike's Peak. A party of emigrants were going across the plains, and they came upon a wagon in a very dilapidated condition, drawn by two or three skeleton horses, or "hair trunks," as they would be called out there, and on the side of the wagon was inscribed these words: "Pike's Peak or Bust." [Laughter.]

With regard to finance, I cannot speak too highly of Col. McLaughlin's arrangements. A year ago he asked us for a certain sum which would carry him up to July, when he thought to make returns. Up to the end of July he had not only not expended that sum, but he had enough to pay costs for August, September, October and November, and still leave a balance undrawn. [Cheers.] I must say that in all his estimates he has always been within the mark, and I believe the estimate he has given us of 3200*l.*, unless special circumstances arise, will enable him to carry on the work till he gets returns next year. If we want this additional money, we trust to be able to raise it among ourselves. Can I give you a greater proof of the belief of the Board in this property than that? [Cheers.] We are going to ask you to allow us to issue the remainder of the priority shares. We might want to issue a couple of thousand of them—I do not think more—but we intend, if we possibly can, to carry this thing to a successful issue without having to appeal to you for more money.

As to the present position of affairs, the new foot dam has been partially completed, and the Colonel writes that we shall have no difficulty in finishing it next season and moving the elevators. We may hope, I think, for a fairly dry season in California. It seems to me that the seasons have altered since I was there. I suppose they are passing through a cycle of wet years. The first year I was in California we had no rain until December 22d, and the second year none until February and March; but now we are having storms in October and November, and heavy rainstorms all through the spring. I was reading a book by Mr. Nottage, of the London Stereoscopic Co., entitled "In Search of a Climate." He was in California in the first three months of this year, and they told him that more rain had fallen during the first three months than had fallen during the whole of 1891 and 1892. No wonder, then, that we were delayed in getting to the river-bed this season. But so far this year the rainfall has been 5½ inches, as against 8¾ inches to the corresponding date of last year, so that I think, gentlemen, our present position is more hopeful than ever it was before. In conclusion, I have no doubt you have come here feeling very sore about this business. We, too, feel sore that we have had a wasted season—no, not wasted, for we have been able to do work for next year. I have had the opportunity of talking of late with a great many shareholders, and find that, underlying this feeling of disappointment, there is a strong belief in the value of this claim and in our general manager, Col. McLaughlin. Strong in that belief myself, I ask you to-day, on behalf of the directors, to pass these accounts, and then to wait patiently somewhat longer (I do not think it will be long) for that success which we believe as strongly as ever will yet crown the persistent efforts that have been made to work this bed of the Golden Feather river. [Cheers.]

Mr. Alfred Borwick, director, said: The struggle to control the flow of that great Feather river against all the forces of nature, as the chairman has said, intensified as they are in that tropical climate, is indeed what might be termed a "battle royal." Col. McLaughlin has had many disappointments and reverses, but I can tell you he is very far from beaten, and if we continue to give him the confi-

dence he has hitherto enjoyed, I am sure you will arrive at the success you all so much desire. Many shareholders have said to me from time to time: "These failures and disappointments are very depressing, and we feel inclined to be sick of the whole concern." I can only tell them, as I tell you, to be of good courage, and I ask them to think what the effect must be on the mind of Col. McLaughlin. He has to conduct this great work single-handed a great part of the year, when malarial fever is about and amid difficulties, of which you have no idea, that have to be encountered and overcome. He has no incentive to carry him on with this work except loyalty to the shareholders and the most ardent desire to redeem every promise that he has made to them. What, then, must be his feelings at the end of a season to find that six months of labor have been profitless and fruitless. Most men would throw up the thing in despair and let the river flow on undisturbed; but he is made of tough fiber, and is one who never says "die," and who will not turn his hand from the plow. The gold is at the bottom of that river, and if it had not been extremely difficult of recovery the river-bed would have been cleared long ago, and it would only become ours now because we have a manager who has a lion heart and possesses all the qualities, mental and physical, which will enable him to bring the work to the success he has prognosticated. [Cheers.]

The chairman said: I propose "That the shareholders desire to express their continued confidence in their general manager, Col. McLaughlin, and thank him and the staff at the mine for their exertions on behalf of the company in the face of adverse circumstances." Adopted by acclamation.

Brief History of Petroleum.

By A. C. Benedict, Assistant State Geologist of Indiana, in *Clay Journal*.

A variety of liquids, variously known as coal oil, crude petroleum, earth oil, maltha, mineral tar, naphtha, steinoll, bitumen liquid, etc., and corresponding in the characters of inflammability and insolubility in water with the animal and vegetable oils, have long been known to occur in many parts of the earth.

The countries most famous for the occurrence of mineral oils are the United States, Russia, Burmah and the West Indies. They also occur in China, India, Italy, Germany, Switzerland, and in limited quantity in France and England.

Chemically, all the various products known as naphtha, petroleum, etc., are closely allied, as they consist mainly of oils of different density and volatility.

The earlier analyses of oils were crude, inasmuch as no further attempt at separating the substances they contained was made than merely heating the oil, cooling the vapors of distillation, and treating the product with sulphuric acid. This sufficed to show that the constituents of petroleum are compounds of hydrogen and carbon. It was not until a comparatively recent date that any advance was made in the chemistry of the hydrocarbons, but now we have a long list of articles of the utmost importance in the arts and sciences derived from the researches of the chemists in this direction.

The earliest analysis of petroleum I have been able to find a record of is that of Winterl, made in 1788, of a black, heavy-bodied petroleum from Hungary, which yielded a colorless oil, a yellow oil, and a buttery mass. The last was probably an impure paraffine. In 1817 the native naphtha of Miano, in the duchy of Parma, Italy, was used for lighting the streets of Genoa. This is probably the earliest use by a city of crude petroleum for lighting purposes. In an account published at that time it is described as being a transparent thin yellow liquid, lighter than water, with a strong, persistent smell.

Bitumens are found of all degrees of consistency and of many shades of color. The naphtha of Georgia, on the Caspian sea, is as colorless as pure water, while the asphaltum from the island of Trinidad is a black semi-solid body called the "bitumen lake." The light, clear oils consist almost wholly of carbon and hydrogen, while the heavier, darker and more solid varieties usually contain oxygen, and frequently sulphur and its compounds, carbon and bituminized carbonaceous matter.

The well-known odor of crude petroleum is nearly always due to bituminous matter, spoken of above, or to sulphur compounds, as sulphureted hydrogen. To the last is due the odor noticeable in the waters of many of the artesian wells.

From the colorless varieties we pass by imperceptible gradations through the heavier and darker varieties of petroleum to mineral tar or pitch, that is generally considered petroleum, in which there is enough bituminous matter either dissolved or suspended to render it black and of a semi-fluid consistence. This mineral tar is intermediate between the light-bodied oils and the solid asphaltum.

New Method of Separating Gold from Impure Amalgam.

J. C. F. Johnson, Adelaide, in the Australian *Mining Standard*.

I had submitted to me lately a sample of amalgam from a mine in West Australia which had proved a complete puzzle to the manager and amalgamator. The Mint returns showed a very large proportion of impurity, even in the smelted gold when retorted only, and the authorities refused to take it, after the first two cakes of 119 oz., which yielded only 35 oz. 5 dwt. standard gold, and 140 oz., which gave 41 oz. 10 dwt. The gold smelted on the mine was nearly as bad proportionately—thus, 128 oz. smelted at the Mint to 87 oz. 8 dwt., and 109 oz. to 55 oz. 10 dwt. The impurity was principally iron, a most unusual occurrence in my experience, and due, as I found on inspection and assay of the ore and mine water, to two causes—an excess of arsenate of iron in the stone, and the presence in large proportions of salts, principally chlorides of calcium Ca Cl_2 , sodium Na Cl , and magnesium Mg Cl_2 , in the mine water used in the battery. The exact analysis of the water was as follows:

Fe CO_3	2.76	grains per gallon
Ca CO_3	7.61	" "
Ca SO_4	8.71	" "
Ca C_2	2797.84	" "
Mg Cl_2	610.13	" "
Na Cl	5072.65	" "

Total solid matter..... 8572.70 = 19 5/8 oz.

It will be seen, then, that this water is nearly four times more salt than that of the sea. The effect of using a water of this character, as I have previously found, is to cause the amalgamation of considerable quantities of iron with the gold, as in this case. I received 10 oz. of amalgam, and, having found what constituted its impurities, proceeded to experiment in its treatment. When retorted on the mize it turned out in a black cake, so impure as almost to make it impossible to smelt properly. I found the same result on first retorting, and, after a number of experiments which need not be recapitulated, though some were fairly effective, I hit on the following, which was found to be most successful, and will probably be so found in other localities where similarly unfavorable conditions prevail. I took a small ball of amalgam, placed it in a double fold of new fine-grained calico, and after soaking in hot water, put it under a powerful press. The weight of the ball before pressing was 1583 gr. From this 383 gr. of mercury were expressed, and five-eighths of a grain of gold was retorted therefrom. The residue, in the form of a dark gray and very friable cake, was powdered up between the fingers and retorted, when it became a brown powder, and afterward calcined on a flat sheet in the open air; result, 50 gr. of russet-colored powder. Smelted with borax, the iron oxide readily separated with the slag; result, 311 gr. gold 871-1000 fine. A second smelting brought this up to 914-1000 fine. Proportion of smelted gold to amalgam, one-fifth. The principal point about this mode of treatment is the squeezing out of the mercury, whereby the amalgam goes into the retort in the form of powder, thus preventing the slagging of the iron and enclosure of the gold, as in the ordinary cake. The second point of importance is thorough calcining before smelting. Of course it would be practicable, if desired, to treat the powder with hydrochloric acid, and thus remove all the iron, but in a large way this would be rather expensive, and my laboratory treatment, though necessarily on a small scale, was intended to be on a practical basis.

They are now treating the amalgam at the mine in this way with great success.

The Southern Oregon Mines.

G. W. Davis, a California mining man, who has been quietly inspecting the southern Oregon gold district, with a view to investment, has been in Portland, where he was interviewed by an *Oregonian* reporter. He believes that if capital were invested in building roads over the mountains and improving the transportation facilities southern Oregon might soon lead the world in gold production. He is of the opinion that many fine prospects, which are really worthless to their present owners, might be developed into paying properties if placed in proper hands and backed by sufficient capital. Many of these prospects, Mr. Davis states, are in such out-of-the-way places that thousands of dollars must be expended on roads before the proper sort of developing machinery can be hauled in. Then another outlay of capital must be made before the investor can get any returns.

"But in my judgment," he continued, "there is sufficient evidence of the presence of gold to justify the expenditure of capital. The surface croppings in a number of prospects I examined are the finest I have ever seen in any part of the country. The success of the Ashland mine indicates what perseverance in developing will do. There are other properties which I think will soon be on an equal footing with the Ashland. The Contenton mine, situated

on Williams creek, about 18 miles southwest of Grant's Pass, was discovered about 18 months ago by a man named Bailey, and now produces a free-milling ore which runs about \$15 per ton. The owners are doing a great deal of development work. They have reached a depth of nearly 150 feet, and have done over 600 feet of tunneling. The mine has been prospected for 800 or 900 feet on the surface, and 400 feet of tunneling shows a continuous vein, the average depth of which is about four feet, and the paying streak shows a tendency to widen. There is an eight-stamp mill on the property.

"I heard a great deal of the Hammersly mine, on Jump-Off-Joe creek, about 16 miles northeast of Grant's Pass, but did not have time to personally investigate it. I understand Messrs. Goodsell & Drew are the owners of this property, and that they have made a rich strike. They have reached a good depth, and drifting has shown that the ledge is increasing in size. There is a small mill on the property.

"Investors, as a rule, do not take much stock in placer mining, but southern Oregon offers some great opportunities in that direction. Nearly all of the best placer claims have been taken up. There are consolidated claims covering hundreds of acres, but they are owned by bankrupt companies, who will not sell out except at a fancy figure. There is a big claim on Grave creek which covers about 700 acres and is owned by Portland parties, I believe. A 15-mile ditch is under construction which will furnish a good supply of water during eight months of the year. It is seven feet in width at the top, three feet deep and gives a supply of 3000 miner's inches. It is expected that the ditch will be finished by February 1st. Most of the placer claims can only be worked a few weeks in the year, owing to the scarcity of water in their vicinity.

"Taking into consideration all of the difficulties in the way, I consider the mines of southern Oregon equal to any on the coast."

Oregon's Mammoth Caves.

Captain A. B. Smith went from Josephine county to Portland lately to submit a proposition to the Oregon commissioners of the Midwinter Fair, says the *Oregonian*. The captain is chief owner of a mammoth cave, whose entrance is twelve miles north of the State's boundary line, and which has been explored for a distance of 22 miles, partly underlying California's surface. The end of the cave has not yet been reached. It is a chain of spacious chambers, some of them being 326 feet in diameter, and the ceiling of none of them being less than 50 feet from the floor. Captain Smith wants to have one of these chambers duplicated in plaster of paris and exhibited at the San Francisco fair as one of Oregon's natural wonders, and that is what he came to see the commissioners about. It would require considerable money to defray the cost of arranging the exhibit, but the captain believes that it would more than clear itself if a small fee were to be charged for the privilege of inspecting it. At the World's Fair there was a plaster of paris imitation of a portion of Kentucky's mammoth cave that earned bushels of dollars for its proprietors, and Captain Smith declares that his cave is as far ahead of the Kentucky cavity in all the elements of attractiveness as Kentucky whisky is in front of Chinese gin as an agreeable beverage.

"We have 600 chambers in sight and an incalculable number to find before we reach the end of the cave," said Captain Smith last evening. "The chambers lie in nine different strata—granite, marble, limestone, redstone and others—and almost every one of the natural apartments contains a marvel of some kind aside from its stalactites and stalagmites. In the 'Lord's Supper chamber' there is an almost perfect facsimile in limestone of the famous painting. The 'fairy chamber' is in a stratum of California diamonds. The 'tornado chamber' is visited by a wind storm every 24 hours. In the 'rain chamber' there is a perpetual drizzle, and the 'steam chamber' is constantly filled with steam from an undiscovered source. A coffin resting on stalagmites is the feature of the 'death chamber,' and the 'bridal chamber' is ornamented with a solid stone four-post bedstead. Then there is 'Sullivan's chamber,' so called because of a mighty arm and fist pendant from the ceiling, and others too numerous to mention, much less to describe. A reproduction of any one of these chambers would prove a drawing card at the Midwinter Fair."

Some San Francisco people of a scientific turn are organizing a party to resume exploration of Captain Smith's cave this winter, and Senator Mitchell is endeavoring to get an appropriation from Congress to enable the Smithsonian Institute to take a hand in the game. The railroad point nearest to the cave is Grant's Pass, 70 miles from the entrance, but a surveying party is now laying out a new road from the cave to Jacksonville, for a distance of 26 miles.

Gold Mining in Chili.

The *Chilian Times* calls attention to this subject in a recent issue, and in view of the great depreciation of silver the question is undoubtedly one of serious interest to most South American countries. To Chili it is of serious importance, and it will be the duty of its rulers, in view of the uncertain future of silver, to do all in their power to promote and develop the production of gold within the limits of that country. Hitherto no practical steps in this direction would appear to have been taken, but the time has surely come when a *laissez faire* attitude in this respect ought to be abandoned, and when enterprise should be encouraged and fostered with the object of utilizing the auriferous resources of the republic. The precious metal exists in its territory in considerable abundance; it is, roughly speaking, found "everywhere throughout a length of 3000 miles," of course not always in paying quantities, but the facts go to show that an immense treasure is there which industry might profitably place at the service of mankind, with every prospect of affording satisfactory returns for the capital and labor employed to win it from the bowels of the earth.

At a recent meeting of the Scientific Society of Santiago, Mr. R. Herrmann, the president of that body, broached an interesting theory in connection with the auriferous deposits of Chili. In the course of an address, alluding to the geological formation of the gold-bearing region in the Transvaal, he suggested that there might be a similarity between it and that of the republic. We quote as follows from our above-named contemporary: "Mr. Herrmann believes that it is very probable there exist in the tertiary formation of Chili beds of auriferous conglomerates. The carboniferous formation, which is one of the oldest of the tertiary formation, is of great area in Chili and extends all the way from Dichato to Magallanes. It is a well-known fact that gold is found in all the rivers and streams in the carboniferous region, and Mr. Herrmann arrives at the following conclusions: 'The rocks upon which the Chilian carboniferous formation rests, and those which divide them, are auriferous, and the inferior stratum in this carboniferous formation is composed of conglomerates. Therefore, it would be worth while to ascertain if these conglomerates contain gold or not, and, if they do, to examine them at different places for the purpose of ascertaining if they contain gold in paying quantities.' " This is the problem that Mr. Herrmann submits to the consideration of the country, and it is to be hoped that his suggestion for the examination for what he believes to be gold-bearing conglomerates may not be ignored by the Sociedad Minera and the government.

Modern methods and machinery have greatly improved and cheapened the processes for the extraction of gold, and to such an extent is this the case that profits can now be obtained from the treatment of low-grade ores, such as, without exploration, are known to be plentifully available in Chili. This is especially so in the central zone, where, in addition, there are accumulated hundreds of thousands of tons of tailings capable of being made to yield a handsome return. The gold is in the country, and the Chilians have both money and industry, if other conditions are provided, foremost among which ranks the necessity for facile means of transportation. From the province of Aconcagua alone untold wealth can be acquired, and the provinces of Coquimbo and Atacama are rich beyond the dreams of avarice. Under the altered circumstances brought about by recent events the Chilians cannot afford to disregard their auriferous deposits, and manufacturers and patentees of mining machinery and methods would do well to supply the Chilians with particulars, for, says the *Chilian Times*, "there are not wanting signs of a reaction in favor of gold mining."

Not long ago some person sought to decrease the yield of a crushing in one of the mills in Amador county by "greasing" the battery, an old trick around mining camps. There are various other ways of making amalgamation difficult or impossible. It may be done by "leading" the ore or the quicksilver or to pour some heavy oil on the dump to be crushed, such treatment having its bad effect as soon as it gets to the mortar. Unless a millman discovers the trick in time he may otherwise run away much of the metal in the ore. The *Amador Ledger* says that in this instance nothing was known as to the condition inside until the cleanup was commenced, when chunks of bacon rind were found mixed with the quartz, the bacon having been worn away by the action of the stamps. The pieces were altogether too large to have got in in any way except by design. The crushing was not improved by the treatment, and such methods will be guarded against in the future. Miners in Amador county are entitled to all they get and never object to striking a "greasy" spot now and then, but this process of extracting fat does not meet with approval.

Scientific Progress.

Water Bacteriology and Sand Filtration.

The importance of bacteriological studies of water supplies have been recognized by scientists for only a few years, and it is only since the recent cholera scare that such studies have received much consideration in this country, except among the advanced students of sanitation. Some facts and reflections in this connection are given in *Longman's Magazine* for December, by Mrs. Percy Frankland, from which the following information has been taken:

"For many years artificial sand filtration was considered by chemical experts as of no value, because it effected so little chemical change in the water. It was used to produce a clear rather than a pure water.

"In 1885 the new bacteriological water tests of Dr. Koch were for the first time applied to the London water supply by Prof. Percy Frankland, resulting in the surprising demonstration that by sand filtration the number of bacteria in Thames river water was reduced 99.2 per cent. Regular monthly examinations of the London supply were afterward made by Prof. Frankland, which, with numerous studies elsewhere, have shown conclusively the value of sand filtration for the removal of bacteria from water."

It is interesting to note in connection with the London investigations that at the time when these results were first published, the public, instead of being reassured by these facts, were greatly alarmed, and it is a matter of history that the mere demonstration of the presence of micro-organisms in drinking water caused a fall in the price of several of the water companies' stocks!

Reference is made to the well-known fact that Altona, with a filtered water supply, almost escaped the cholera epidemic which recently raged in the adjoining city of Hamburg, with an unfiltered supply from the same river.

Mrs. Frankland states that, while there can no longer be any doubt of the value of sand filtration, "the slightest imperfection in its manipulation is a constant menace during any epidemic"—a statement, remarks the *Engineering News*, which is obviously just as true of any other form of water purification. Prof. Frankland's London studies show that during the winter the unfiltered water is generally richest in bacterial life, and that at the same time the largest number of bacteria are present in the filtered water—facts that demand great care in the winter management of filters. In conclusion, Mrs. Frankland states:

"The bacteriological methods for the examination of water, although when first introduced but a few years ago were lightly looked upon, and by many opposed, have now become of paramount importance in all questions of water purification. The immense mass of evidence of a purely bacteriological character which was recently taken, and, indeed, required by the Royal Commissioners on the London water supply, indicates clearly enough the change which has taken place in the public estimation of the value of these methods, and it is highly significant that in their report the commis-

sioners lay stress upon the importance of extensive storage and efficient filtration, two factors the meaning and worth of which rest almost entirely on the results of bacteriological research."

Detecting Mine Gases.

The eminent French scientist, Gaston Tissandier, describes an absolutely new method of determining the quantity of foreign gas contained in air by the passing of the gaseous mixture through sonorous tubes. The invention is credited to M. E. Hardy, a distinguished French physician, who calls it the "formenophone," and intends it primarily for the detection of fire-damp in mines. One of the best detectors of gas yet known is the safety lamp, but it has the radical objection that the aureole around the flame, which indicates the presence of dangerous fumes, does not show itself until such a quantity of gas is present as constitutes a critical danger. The formenophone, on the contrary, gives the indication in a few seconds. The principle on which it is based is that when two organ tubes, giving the same pitch, are subjected to the influence of two equal blasts of pure air the sound produced is identical. But, everything else being equal, if one of the tubes is blown into by a mixture of air and gas of different intensity, the sound of the tube is correspondingly modified, and the vibrations produced are more or less frequent as more or less gas is mixed with the air. This occurs with such unvarying results that Mr. Hardy has been able to lay down a regular scale of vibrations and their significance for the guidance of those using his invention. The apparatus consists, briefly, of two blowers, or pairs of blowers, enclosed in air-tight metallic envelopes. One of these cases contains pure air only, and to the other is conducted by a pipe the air of the part of the mine to be tested. The air in each receptacle is blown by the disengagement of a weight on the top of the bellows, whereby downward and forcible pressure is immediately produced into the organ tube with which each receptacle is provided.

The resultant sound is so intensified by a special adaptation of the microphone and telephone that it can be distinctly discerned, and a comparison of the difference in sound of the two tubes gives an absolute indication of the quantity of gas in the air tested.

Soap-Bubble Solution.

According to a communication recently made to the Academy of Sciences, the following solution makes very thin and permanent bubbles:

Yellow resin..... 10 grammes
Carbonate of potash..... 10 "
Water..... 100 c. c.

Boil until completely dissolved, and before use dilute the solution with four times its volume of water. It is somewhat difficult to float soap bubbles upon carbon dioxide because if you managed after a score of trials to free your bubble from the pipe on which you blew it the bubble usually bursts the moment it touches your heavy gas. You must remove every trace of hydrochloric acid, which is carried over with the gas, by washing, the presence of this acid being fatal to the life of a soap bubble.

FOR SALE CHEAP.

TEN 18" diam. suction and discharge

CENTRIFUGAL PUMPS,

WITH ENGINE ATTACHED.

—Together with—

NINE UPRIGHT BOILERS, 55" diam.

—Also—

TEN FOOT VALVES, and about 300 feet of 18" diam. STEEL FLANOE PIPE in 4, 8 and 12 foot lengths.

This machinery is practically new, and was built especially for use as a working plant. The pumps have each a maximum capacity to deliver 60 tons of water per minute. The plant will be sold very low as a whole or separately. These pumps are suitable for irrigating purposes or under any conditions where a large volume of water is required to be moved quickly and cheaply. For prices and other particulars, address

GOLD AND SILVER EXTRACTION COMPANY, OF AMERICA.

LIMITED.

MacARTHUR-FORREST CYANIDE PROCESS.

CAPITAL, £110,000 STERLING.

To MINE OWNERS and others having Refractory Gold and Silver Ores hitherto untreatable at a profit, the MacARTHUR-FORREST CYANIDE (Patent) Process of Gold and Silver Extraction offers a solution of the difficulty.

The chief features of this process are
Simplicity, Economy in Working and Small Cost of Plant.

OFFICE:

McPHEE Building, DENVER, COLORADO

NOTICE TO MINE OWNERS!

The undersigned will have in operation at the Midwinter Fair a complete free gold and concentrating plant, where they will work, free of charge, any lots of ore from one to five tons.

For further information address them at 213 First Street, San Francisco.

F. A. HUNTINGTON.
GEO. E. WOODBURY.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for \$3 per volume of six months. Per year (two volumes) \$5. Inserted in Dewey's patent binder, 60 cents additional per volume.

PATENT Double-Acting Cornish Plunger.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER.

AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, beedee doing away with heavy balance bobs often carrying from 25 to 50 tons of balance Works with 25 per cent less power. First outlay about one-third less. Suitable to any underly or downright shaft. Friction reduced to a minimum. Couples less space in the shaft. Has been tested about a year and proved to work satisfactorily in every respect.

GUARANTEED TO GIVE SATISFACTION.

Special attention is called to this new feature in the drainage of mines and raising water generally, by which a continuous discharge of water is produced on the up stroke and down stroke, instead of on the down stroke only, which is effected by very much less than one-half the weight of machinery now in use. When the ordinary pump becomes too small for the work it can be replaced by the new one, using the same rod and column, and doubling the discharge of water, a most important advantage in small shafts where there is not room for a larger pump.

Apply to WM NANCE, Grass Valley, Nevada County, Cal.

NOTICE TO GOLD MINERS! SILVER-PLATED AMALGAMATED PLATES For SAVING GOLD!

IN QUARTZ, GRAVEL, OR PLACER MINES. MADE OF BEST SOFT LAKE SUPERIOR COPPER AT REDUCED PRICES.

Our plates are guaranteed, and by actual experience are proved, the best in weight of Silver and durability. Old Mining Plates Replated, Bought, or Gold Separated. THOUSANDS OF ORDERS FILLED.

Mechanical Progress.

Greater Speed for Steamships.

Although some of the schemes for shortening the time needed to cross the ocean are chimerical, there is a fairly close agreement among reputable experts as to the possibilities of gain upon the present speed of our fastest steamships. A few months ago the designer of the *Parls*, J. H. Biles of Glasgow, indicated in the pages of "The North American Review" the means by which, in his opinion, this end may be attained. Since that time the engineer-in-chief of the United States Navy, George W. Melville, has read a paper on a kindred subject before the Society of Naval Architects and Marine Engineers. It was also discussed a few weeks ago by Mr. Richard Newman of Philadelphia, president of the engineering section of the Franklin Institute, in an address before that body.

No one seems to expect any special improvement in the steam engine, so far as its form or principle is concerned, but by using nickel-steel instead of mild steel for its construction, greater lightness and strength would be secured, remarks the *New York Tribune*. Still more radical changes in boilers are recommended. At present the latter are too heavy. The multi-tubular type, already used for some yachts and torpedo-boats, would give more steam for the same space; and though individual specimens of this sort, especially the locomotive form, are objectionable because the motion of the ship is liable to bare portions of the uppermost flues at times, confidence is expressed in the feasibility of so modifying the system as to adopt it to marine service. By forced draft and a blast of air heated by the smoke and escaping gases combustion may be made more complete, and more power got out of the same amount of coal. Mr. Newman thinks that boilers might safely carry 500 or 600 pounds pressure; at present 250 or 300 is about the maximum. Mr. Melville regards a piston speed of 90 strokes a minute, which has been gradually attained of late years, a limit that may easily be surpassed. The engineer-in-chief, too, recommends higher smokepipes for increasing the natural draught.

Mr. Newman points out the great advantage which oil possesses over coal for fuel. Twice as much work can be got out of the same bulk; and he wonders why America and Western Europe have been so slow in imitating South and Eastern Russia. Steamers on the Volga and Caspian have long used with great success the waste products resulting from the manufacture of petroleum. The saving of space would admit of the use of more powerful machines and larger freight service; and oil requires less labor than coal for stoking. With the general improvements here suggested, and without change of model, Mr. Newman believes that it would be possible for steamers to make 25 knots an hour.

Gas from Peat.

A report by T. C. Linton, engineer of the Leith (Scotland) works, was submitted at the last meeting of the Edinburgh Gas Commissioners as to the manufacture of gas from peat. A quantity of black peat was procured from the Wellington Reformatory Farm, Penicuik, but as the results from it were entirely worthless, owing not only to the quality of the peat, but to its being in an undried state, it was resolved to procure other samples of peat dried in the usual manner. One of these samples was procured from the Leadburn district, the other was obtained from Orkney. The results proved that even the best quality of peat could not compete at all with coal for gas-making purposes. There were, moreover, other drawbacks besides the hopelessly inferior results yielded to be considered. The

excessive proportion of carbon dioxide produced (from six to seven times as much as in crude coal gas), which had to be removed from the gas, would make the cost of purification enormous.

Automatic Gem Separator.

An automatic gem separator, described by William S. Lockhart, has been devised for the purpose of selecting precious stones from the worthless gravel with which they were associated without the intervention of hand picking as now practiced, thus avoiding the danger of loss by theft and other disadvantages. In South Africa, Burmah, Siam, Ceylon and other parts of the world the systems of washing vary to some extent, but all systems resolve themselves finally into the picking over of a concentrated deposit of clean-washed gravel for the gems it may contain, and it is, says Mr. Lockhart, at this point that the separator comes in to perform what has heretofore been done by hand.

To Make Glass Pipe.

A system of manufacturing glass pipe by rolling molten glass down in flutes, or grooves, and using a core to complete the formation of the tube, has been proposed by P. Sievert, of Dahlen, Saxony. Molten glass is poured from a reservoir, or hopper, into the bite of two rollers. The rollers are placed horizontally, each being provided with grooves in which is placed a core of suitable dimensions. When the core is moved downward the molten glass follows the movement and forms a tube, the dimensions of which are determined by those of the ring-shaped space between the contours of the grooves and the core. The circumferential velocity of the rollers regulates the speed at which the core is lowered.

Uses of Coal Oil.

Coal oil is used for fuel not only under steam boilers on land and afloat and in locomotives, but in furnaces for making crucible steel. A plant of this class was recently described by W. E. Crane of Waterbury, Conn., before the American Society of Mechanical Engineers. Regarding such use of oil with engines the *Iron Age* recently raised an interesting point. In summer oil will flow freely through the supply pipes; in winter extra heat may be required to keep it in a fluid condition. Broken pipes and other such repairs might easily modify the economy of using that sort of fuel.

Longest Drawbridge Span.

The longest drawbridge span in the world, so it is claimed, is that now being constructed between East Omaha and Council Bluffs. It measures 520 feet from end to end. That at New London, Conn., is 503 feet long and one over Arthur Kill, Staten Island, just 500. The new drawbridge of the New York Central, over Harlem river, has an extent of only 389 feet, but it provides for four tracks and is the heaviest one in the world, weighing 4,400,000 pounds. The one at East Omaha will weigh, when completed, about 3,000,000.

Fine Grinding Process.

A lathe hand has been studying on the grinding problem, and has discovered that there is always a slotted feed shaft just under the lathe bed that will give a good chance to work from, says the *Chicago Journal of Commerce*. A small pulley is used, slip-keyed to this shaft, that keeps right along with the lathe carriage, and belted up to such an extent that a high speed is attained for a grinding spindle. In this way some fine grinding can be obtained without any of those overhead contrivances that are so unsightly in a machine shop.

Useful Information.

What Pearls are Made of and Where They are Found.

Very few people are aware that the pearl oyster is not in any way like the oysters which we eat. It is of an entirely different species, and, as a matter of fact, the shells of the so-called pearl oyster are of far more value to those engaged in "pearl fishing" than the pearls, says *Harper's Young People*. There are extensive pearl fisheries in the Gulf of California, and some of the finest pearls have been taken from these waters. In 1881 one pearl, a black one, was sold for \$10,000, and every year since that time many pearls have been taken from the beds in the Californian gulf valued at \$7500 each. But such "finds" are very rare, and, as a rule, the pearls which are brought up are of very little value. The shells, however, are very valuable; most of them are shipped to Europe, where they are manufactured into ornaments, knife handles, buttons, and various other articles for which "mother of pearl" is used.

Another fact concerning the pearl oyster and the pearl itself is very little understood. I have seen in books of instruction, both in this country and in England, the statement that "the formation of the pearl in the oyster shell is caused by a disease of the oyster;" and this statement is more or less generally believed, as is also the erroneous inference to be drawn from it, that the oyster referred to is the edible oyster. The mother of pearl is nothing more than a series of layers of nacreous matter deposited by the oyster upon the interior of the shell, and the pearl itself is a perfectly accidental formation. It is caused by a similar deposit of nacre around some foreign object. This foreign substance may be a grain of sand, a parasite or some similar object; but most authorities agree that it is more usually an undeveloped egg of the oyster around which the natural deposit is thrown.

The largest pearl ever found measures two inches long and weighs three ounces. This is of Eastern origin. The largest found in the Gulf of California did not exceed an inch and a quarter long, and was somewhat larger than the egg of a bluebird. Many of the Californian pearls are black and speckled. These are considered more valuable than the white pearls in Europe, but the most highly prized pearls of all are pink.

Some Interesting Dates.

The apple-parer was given to the public in 1803. At the present day, one Eastern firm makes over 27,000 a year.

Matches were first invented in 1839, and it is estimated that 75,000,000 a day are burned by the people of the United States.

The blast furnace was devised in 1842. In 1890 the United States alone made 9,000,000 tons of iron and 4,277,000 tons of steel.

Washboards with a metal face were patented in 1849; now the backs of the American women are weekly bent over 6,000,000 of these useful articles.

Window glass was first used in modern times in 1557. Now the consumption of plate glass alone exceeds 6,000,000 square feet in England and 9,000,000 in the United States.

A machine for making tacks was patented in 1806, but not put into practical use until near the middle of the century. Now the world consumes 50,000,000 tacks a day.

The nail machine was invented in 1775. At the present time it is estimated that 4,000,000,000 nails are annually made by machinery in Great Britain alone, and from a fourth to a half of this number in the United States.

The first forks made in England were manufactured in 1608. Their use was ridiculed by the men of the time, who argued

that the English race must be degenerating when a knife and spoon were not sufficient for table use. Last year a Sheffield firm made over 4,000,000.

Breech-loading rifles were invented in 1811, but did not come into general use for many years. It is estimated that over 12,000,000 are now in actual service in the European armies, while 3,000,000 more are reserved in the arsenals for emergencies. Statisticians say that there are 100,000,000 guns of all kinds in the world.

The railroad system of this country began in 1827. Now there are 214,528 miles of track in the United States, and 354,310 in the world. The number of passengers carried by the United States railroads in 1892 was 555,025,802, and the total earnings were \$1,138,024,459. The capital stock was \$4,800,176,651, and the dividends \$90,719,757. The number of men employed was 784,285.

The harvester was invented by McCormick in 1831. Since that time this machine has been brought to such perfection that, it is said, it will cut and bind an acre of grain in 45 minutes. To such an extent has machinery superseded hand work in the grain farms of the Northwest that it is estimated that the labor of one man will raise enough grain to support a thousand men for a year, while the labor of a second will transport it to market, and that a third will prepare it for food.

Curious Facts.

Somebody who claims to know says that a child three years old is half the height it will ever be.

A bat can absorb and digest in one night three times the weight of its own body. Bats never have more than two little ones at a time.

An English officer, being hypnotized in South Africa, began to speak in Welsh, which he had known as a child, but forgotten for 20 years.

The idea of an ancient tropical continent at the south pole, uniting South America, Madagascar and Australia, is arousing considerable interest and discussion in scientific circles.

A break in the main water pipe in a street in Tombstone, Arizona, recently, was found to have been caused by the roots of a tree which had grown around the pipe and crushed it so that it burst.

The rudder of the Cunard steamship *Campania* consists of a single plate of steel 22 by 11 feet 6 inches and 1 1/4 inches thick. It was rolled at Krupp's German gun factory.

In South America among the mountains the evergreen oak begins to appear at about 5500 feet, and is found up to the limit of the continuous forest, which is about 10,000 feet. The valuable cinchona tree, from which Peruvian bark is obtained, has a range of elevation on the mountain slopes running from 4900 to 9500 feet.

A new pneumatic tire brought out in England, which is described as a really good thing, has a pad of prepared cotton wool covered with soft cloth, which is inserted between the cover and air chamber, rendering it almost impossible to puncture it even with a sharp awl. The weight of this pad is 50 ounces, and the cost is trifling.

Water boils at different temperatures, according to the elevation above the sea level. In Baltimore, water boils practically at 212° F.; at Munich, in Germany, at 209 1/2°; at the City of Mexico, in Mexico, at 200°; and in the Himalayas, at an elevation of 18,000 feet above the level of the sea, at 180°. These differences are caused by the varying pressure of the atmosphere at these points. In Baltimore the whole weight of air is to be overcome. In Mexico, 7000 feet above the sea, there are 7000 feet less of atmosphere to be resisted; consequently less heat is required, and boiling takes place at a lower temperature.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen.
First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from hanging on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

BOOKS ON ASSAYING.

By C. H. AARON.
Part I.—Gold and Silver Ores.
SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning.
The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:
Preface; Introduction; Implements; Assay Balance; Material; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assay; Examples of Dressing; The Melting in Crucibles; Scorching; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Crust; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.
The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1893. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.
Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.
SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion; Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:
Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhart's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.
One of the methods given for the Assay of Copper is new, original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.
Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

Electricity.

Electric Cooking at Redlands.

Electric cooking is being tried at Redlands, Cal. The *Facts* says: "While passing the office of the Electric Light Company the other day a *Facts* representative was attracted by the appetizing odor of coffee. On investigation he found that the company's officers were demonstrating the efficiency of their new line of electric cooking apparatus. President Sinclair, while in the East, partook of a dinner cooked wholly by electricity, and is more than ever convinced of the efficacy of the electric fluid as a fuel for cooking. As we examined the various utensils, noted their simplicity, safety and convenience, we were convinced that where electric power can be secured at reasonable rates, the old wood and coal stoves for cooking will be supplanted with electrical appliances.

"Another direction in which we learned that electricity is being applied is in laundry machinery. Here there is a great saving of heat and discomfort, while in residences already using electricity for lighting, the additional cost is trifling.

"Assuredly this is the electric age, and if all indications are correct, we are yet only on the threshold of its development."

In Behalf of the Trolley.

The International Tramways Congress, which met last autumn at Buda Pesth, passed the following resolution bearing upon electric tramways: "The electric tramways with direct current from a central station have given satisfaction on several lines on the continent now in operation, and this applies both to tramways with underground and to tramways with overhead conductors. The statistical figures hitherto available are, however, not sufficient to form a definite opinion about the financial aspect. The employment of electricity is, however, in the interest of the public, as not only will a greater speed be obtained, but it will also be possible to carry a larger number of passengers." The congress asserts that, in its opinion, the electric system of working should, therefore, be recommended to authorities and tramway administrators. The congress further holds that the authorities should endeavor to make it possible for tramway companies to undertake the expense of a change from horse to electric traction by extending the concessions, and permitting the use of overhead conductors.

Parcel Cars.

Electrical parcel cars, somewhat resembling in shape the post vans, will soon be seen in the streets of London. The novelty in the construction of the cars consists in placing the accumulators underneath and outside the body of the vehicle. It is estimated that for every mile run by an omnibus of one of the great companies the cost for horse traction is exactly 5d, while the cost for running an electric car would be just 2½d. The accumulators have been made so that they can be charged with electricity sufficient to last for four hours' work. The same electrical arrangement is about to be applied to broughams and private carriages.

The Erie Canal Experiments.

The closing of the Erie canal for the winter, remarks the *Electrical Engineer*, has brought temporarily to an end the recently begun experiments to apply the electric motor for canal-boat propulsion, which can be resumed at the opening of navigation next spring. The abandonment of the trolley pole in favor of the over-running trolley, similar to that used on the early Van-Depoele roads, was a foregone conclusion, the freedom of motion of the boat it permitted giving ample proof of its adaptability to this purpose. It appears also that the

matured plans of the promoters of the enterprise involve the application of high-tension alternating current reduced to a safe working pressure at the trolley lines for alternating motors.

A Failure of Arresters.

Recently in Milwaukee four hundred telephones were rendered useless as a result of a trolley coming in contact with a telephone wire, the strong current of the former being conducted into the terminal room of the telephone exchange. A vertical strip of current arresters four feet high, on each side of which are trained the subscribers' wires, was speedily ignited and it burned to the top. Twenty-five cables containing subscribers' wires, which are carried from the arresters to the switchboard, were destroyed, rendering about 400 lines unserviceable. The failure of the arresters to act is a mystery.

Electric War Engine.

A new engine of war has been invented by M. Turpin, the chief point of the invention being the application of electricity. A very light wagon, drawn by two horses, contains two groups of projectiles, and with the aid of four gunners, four charges can be fired off in a quarter of an hour, each throwing 25,000 missiles over a surface of 22,000 square meters. In spite of its extraordinary power, the invention is said to be perfectly simple in design.

Hypnotism in Disease.

The chief arguments used against the employment of hypnotism in disease are, first, that it subordinates and enervates the will; second, that it renders the patient liable to be influenced by persons of evil intent; and third, that only nervous or hysterical persons are subject to its influence, says James R. Cooke, M. D., in *Arena*. My own experience is that it may be used without injurious effects, and also that it may take the place of narcotics in a large number of cases in which they are now used. I have myself used it with advantage in delirium, in insanity and in chronic alcoholism. I have successfully treated one case of kleptomania and two cases of excessive irritability of temper. At the same time hypnotism is a two-edged sword. Wielded by an unskilled hand, it may cut both ways deep into the faculties of intellect and into the nervous system generally. Also, it should never be used save by a skilled hand upon patients of an unbalanced mind accompanied by what is known in medical parlance as *paranoia*. In my treatment of a perfectly healthy, calm, intelligent, unimaginative man, whom I operated on 51 times, I found that the diapason of his whole mental and emotional system would give forth concordant sensations of pleasure or discordant sensations of pain, at the will of the operator.

Summing up, I would say that in hypnotism, as with every other new remedy, there is great danger that, on the one hand, it may be used indiscriminately, or, on the other hand, be scouted by a senseless skepticism. It has, beyond doubt, its definite limits of usefulness, and the medical man of the present day, realizing the futility of many of the old methods of treating disease, should keep his mind open to the reception of every new discovery.

Good Lemonade.

For a quart I take the juice of three lemons, using the rind of one of them. I am careful to peel the rind very thin, getting just the yellow outside; this I cut into pieces and put with the juice and powdered sugar, of which I use two ounces to the quart, in a jug or jar with a cover. When the water is just at the tea point I pour it over the lemon and sugar, cover at once and let it get cold. Try this way once, and you will never make it any other way.—Scientific American.

STAMP MILLS.

VULCAN WIRE ROPEWAY

for Conveying ORE, CORDWOOD, ETC.

SNYDER MINE,
KENNETT, CAL.

In reply to inquiry as to how Tramway is doing, am prepared to state that it has given ENTIRE SATISFACTION IN EVERY PARTICULAR.

JUDSON TRAMWAY CO., POMEROY, WASH.
It will give us great pleasure to recommend your Ropeway and your Company as well to any persons who may be thinking of erecting Ropeways.

VENTANAS M & M. Co. VENTANAS, MEX.

We take pleasure in testifying to the successful operation of the Vulcan Wire Ropeway furnished us by your company. It easily transports the required quantity of ore from mine to mill and has given us no trouble whatever.

VULCAN IRON WORKS,

GAS WORK A SPECIALTY.

Coast Industrial Notes.

—English stockholders propose to re-organize the Bear Valley Irrigation Company in San Bernardino county.

—The California Sugar Refinery, employing between 800 and 900 men, which has been idle for six weeks, has again started up.

—For the first time in the history of the San Francisco and San Mateo Electric Railway the operations are showing net earnings sufficient to pay the interest on the bonds. The income, over and above all operating expenses, is reported to be \$5500 a month.

—It is said that the Armour Packing Company is contemplating the establishment of a packing-house in Nogales, Sonora, where can be put up for Mexican consumption the beef of Sonora. The low price of cattle there should make that industry a profitable one.

—The Tubbs Cordage and Rope Works are to resume after a shut-down of nearly four weeks. Fifty-three girls and 100 men are employed in this establishment. A reduction in the pay of the operatives has been announced, and those going to work again will be paid 25 cents each per day less than the old rates.

—The Gold Ridge Consolidated Mining and Milling Company has filed articles of incorporation. Principal place of business, San Francisco. Capital stock, \$10,000,000, with Louis E. Gray, Matt O'Donnell, C. M. Jennings of San Francisco, B. M. Lawrence of San Bernardino and John A. Henninger of Oakland as directors.

—Two hundred men are to be put on at the Pacific Rolling Mills, which have not been operated for a month. Three months' work is awaiting the employees of the mills, and other contracts will most likely keep the rolling-mills in operation for some time longer. The rate of wages at the mills has been modified 10 per cent.

—The farmers of Lake Washington and Duwamish basin, Wash., are petitioning the King county commissioners to drain their lands. They suffer a good deal from floods, and suggest as the most feasible method of relief that Cedar river be turned into Lake Washington, and the outlet from the latter into Lake Union be deepened and enlarged.

—Receiver Ira Bishop of the Piedmont Cable Company, Oakland, proposes to reduce the operating expenses at least \$12,000 a year by changing the road from Eighth and Washington streets to Mount View Cemetery from a cable to an electric line. The motive power of the Piedmont branch from the power-house will still be a cable, owing to the heavy grades on that line.

—W. F. Whittier, of the firm of Whittier, Fuller & Co., has retired from business in consideration of the sum of \$250,000, paid by his former partner. The bonus is said to be the largest ever paid to any individual in the history of commercial transactions in the United States. Under the terms of the agreement Mr. Whittier has promised not to engage in business again for a term of five years to come.

—Professor Burkhalter of Chabot Observatory, received word from Paris to-day that the great Arago medal, with 1000 francs, had been conferred on Professor Barnard of the Lick Observatory. The medal is given by the French Academy of Sciences for his discovery of the fifth satellite of Jupiter. It has only been conferred once before, and then on the illustrious French astronomer Leverrier for the discovery of Neptune.

—The Gila Valley, Globe and Northern Railway, which is to be constructed, will run from Bowie, Ariz., on the Southern Pacific, to Globe, 130 miles, passing through the Gila valley in Graham county, one of the richest in Arizona, where now over 30,000 acres of land are cultivated. Garland's construction outfit is now en route here from Ogden, and will arrive on the 1st prox., when work will begin. This road will open up a fine agricultural valley. It runs 70 miles down Gila river, ending at Globe, one of the richest mining districts in the territory.

—The extension of the Sacramento-street cable road from Central avenue to Lake street, and along Sixth avenue to Golden Gate Park, will be ready for passengers when the Fair is formally opened. As the roadbed stands at present it is finished, only a turntable is needed at the park terminus, and that will be moved in a night and put into place very quickly. The cable will be joined with the McAllister-street cable, which extends to Seventh avenue, one block farther west than the new terminus. This will be the first instance of a connection between the Market-street Company and any other line in this city.

—It would be difficult to convince the average man that fir is a stronger wood than

oak, but such has been proved by actual tests that were made by a fair and impartial committee appointed for that purpose, says a Tacoma paper. The timbers used were each two by four inches and four feet long, both ends solidly braced and the weight applied in the middle of the span. Yellow fir stood a strain of 3062 pounds, common Oregon oak, 2922 pounds; fine-grained yellow fir from near the butt, 3535 pounds; and the best Michigan oak snapped with a strain of only 2428 pounds. The tests were made by the Northern Pacific Railroad Company at Tacoma, Wash.

—The corps of United States Surveyors under John O. Rice, which has been employed resurveying lands in the mountains north of San Bernardino, has been compelled to suspend operations for the present on account of the snow impeding its progress. It is now camped at the foot of the mountains in the orange groves at Highland and does not expect to be able to resume work until April. Mr. Rice says that there are fine forests of fir and pine on 200,000 acres of land included in its survey, and some of the land is good and will raise profitable crops of apples, cherries, and in the lower foothills, olives.

—A new company is to be incorporated which will take the place of the Oakland Contracting Company, a corporation which with J. P. Cochran as manager, has done much street paving during the past five years. The capital stock is set at \$250,000, of which \$100,000 will be paid up. The name will be the Oakland Rock Company. A ten-year lease has been taken of Iron-rock mountain, a deposit of trap rock about three miles beyond the Berkeley line, and a ten-year contract made with the California and Nevada Railroad Company for transportation. A spur track about 3000 feet in length will be built toward the quarry; from the end of this a tramway 3000 feet long will be constructed. Iron-rock mountain is on the old McAvoy ranch.

—A bridge on the North Pacific Coast Railway, across Austin creek, near Cazadero, Sonoma county, gave way last Monday, precipitating Engine No. 6 into the water, and seven lives were lost. The water in Austin creek is 20 feet above its ordinary level and was rushing faster than it had been known to do in twenty-five years. Before the bridge collapsed the water was up to the rail and speeding like a cataract. The trestle was a new and apparently a strong one; but it seems that the piling on which the span rested was driven into the soft river gravel which was washed away by the flood, thereby leaving no support for the cross-beams. Therefore, when the weight of the engine came upon these latter the entire structure collapsed, precipitating the engine and its entire crew to the bottom.

The San Joaquin Land and Water Company, after six years of litigation among the stockholders has elected a new board of directors with a majority of the men who have been opposing the management, and the great project to bring Stanislaus river water in through a system of canals will be carried forward under a new directory. The new board of directors is composed of Colonel G. B. Sperry, W. C. White, Charles Belding, R. E. Wilhort, J. R. W. Hitchcock of the new forces, and N. S. Harrold, H. W. Cowell and A. M. D. McIntosh of the old crowd. The company owns valuable water rights near Knight's Ferry and has expended \$207,000 in the works, having a dam, several tunnels and a long line of canal nearly completed. The estimated cost of completing the work will be \$400,000, and the canals will carry water to 150,000 acres.

Every Inventor Wants a Good Patent

Or none at all. To secure the best patents inventors have only to address DEWEY & Co., Pioneer Patent Agents, No. 220 Market St., San Francisco.

There are many good reasons why Pacific Coast inventors should patronize this Home Agency.

It is the ablest, largest, best, most convenient, economical and speediest for all Pacific Coast patrons. It is the oldest and most reliable of the American continent, most experienced, and every way reliable.

It has the largest library of Patent Law books, American and Foreign Patent Office Reports, scientific and mechanical newspaper files, latest works on science, art, inventions, and mechanical and other new discoveries.

Conducted from 1863 by its present owners (A. T. Dewey, W. B. Ewer and Geo. H. Stroug) this agency has the best knowledge of patents already issued, and of the state of the arts in all lines of inventions most common on this coast.

Patents secured in the United States, Canada, Mexico, all British colonies and provinces, England and other civilized countries throughout the globe.

Caveats filed, assignments duly prepared, examinations made, and a general Patent Agency business conducted.

Established and successfully and popularly conducted for nearly thirty years, our patrons number many thousands, to whom we refer with confidence, as men of influence and reliability. Old and new inventors are cordially offered the complimentary use of our library and free advice, etc. No other agency can afford Pacific States inventors half the advantages possessed by this old, well-tried and experienced firm.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

AT THE ARGONAUT.—*Ledger*: The Argonaut Mining Company has come to work with a will and is now advancing with its shaft at the rate of 20 feet per week. Three shifts of four men each are working in the mine; one man is running the engine and doing the blacksmithing, while one is in the carpenter shop. These with J. B. Francis as foreman constitute the working force. They have on the ground enough timbers, logging, wood and other supplies to sink the shaft 500 feet. The buildings so far erected consist of an engine house, which contains a donkey hoisting engine, a blacksmith shop, 24 x 24 and a carpenter shop, 12 x 24, the latter two being under one roof of corrugated iron, with sides of the same material. The Argonaut people have gone into the business of finding a mine with a determination to penetrate the bowels of the earth and thoroughly prospect the wealth of their ledge ore. They estimate the cost of their shaft with all accessories of development, to the distance they expect to have to go at \$100,000, and are prepared to expend that amount in its construction, not extravagantly, but economically. The business of developing a mine on the mother lode where depth has to be attained, is a very serious matter and requires mining ability as well as capital, both of which are found in the management of the Argonaut.

Calaveras.

TIMES LIVES.—*Prospect*: Mining throughout the entire county has taken a lively turn of late, and many mines wherein for years had not been "heard the sound of ax, hammer or other tool of iron," are now the scenes of lively operations, and it is safe to say that the bullion production of this county for the coming year will be greater than ever.

At the Dora mine at Esmeralda, a five-stamp mill is being put up and a road has been graded leading from the mine to the mill. The ledge in this mine is about two feet in width and the rock is very rich. It is the intention of the company to run a tunnel into the hill from where the mill stands which will tap the ledge about 400 feet from the surface.

The shaft in the Cunico mine opposite old San Domingo camp has reached a depth of about 400 feet. The ledge is about eight feet in width, and a great deal of the rock, which is exceedingly rich, is worked in a mortar.

The Austrian mine is situated on Indian creek, about a quarter of a mile above Frederick's place. The mine is worked by a tunnel several hundred feet in length and the rock is worked in an arrastra. The vein has paid from the very grass roots down, and the owners—Messrs. Vosovich and Tremontini—who have been working it for the past five or six years, have each accumulated quite a snug amount of money.

The Maria mine at Esmeralda has been bonded by the owner, John Saltuari, to San Francisco parties who have prepared to work the mine on an extensive scale. The shafts and tunnels have been cleaned out and re-timbered, a blacksmith shop built, a new road dug leading to the mine, and everything is in readiness, awaiting the order to start. The rock is very rich in free gold and sulphurets, and it is the intention of the company to send specimens of their ore to the Midwinter Fair.

F. J. Horswill has commenced operations upon his mine near Barker's, which has been idle for about a year. A tunnel about 1500 feet in length will be run to tap the gravel channel. Three hundred feet of the proposed distance has already been run.

Work on the Gold mine at Central Hill, which was recently bonded to F. Schaal, is being pushed with activity. A three-stamp mill, tramway and all the necessary buildings have been erected. A tunnel has been run 200 feet, very rich gravel struck, and the outlook is very encouraging.

THE MOSER MINE.—*Chronicle*: Few of our mining men realize the fact that we have a "big mine," in this property. Main tunnel on lead is now 400 feet north of south end and shows a strong lead running cross the formation, or country rock, and averaging five feet thick. About 100 feet apart the tunnel is provided with up-raises each with substantial chutes, in which up-raises three lines of tunnels are run, all being securely timbered with "square sets." The workings show that none but skilled miners have been employed, and, judging from outside appearances, one can see that the manager understands his business. The mine is provided with a first-class eight-stamp mill, Tulloch concentrators, Challenge feeders, Dodge rock breaker, etc., all in good order, and is kept steadily running under the able management of that veteran millman, George Ward. Rock is supplied by the foreman of the mine, Wm. H. Currow, a practical miner and a man of good judgment.

To the Superintendent, Wood T. Harris, Esq., is due the success of the company.

El Dorado.

TO DEVELOP MINES.—*Democrat*: It is reported that Alvinza Hayward, the successful mining man and one of the owners of the Oro Fino mine, contemplates opening and developing the mining property owned by him near Indian Diggins, this county, at an estimated cost of \$75,000. Some of the best mines in El Dorado county are to be found in that district, and should this gentleman, with large experience and almost unlimited capital, open up such an enterprise this spring, Indian Diggins would experience a revival of the prosperity of early days.

Nevada.

GRANITE HILL MINE.—*Telegraph*: The Granite Hill mine is now looking just about as well as it was expected to look at the depth to which it has attained. The shaft is still going down and the ledge is widening as depth is attained.

EAGLE BIRD MINE.—*Telegraph*: There is quite an important strike in the Eagle Bird mine. It is stated that a two-foot ledge has been found in the 700-foot level, and that the mine is looking well wherever the drifts are being run. The shaft is being sunk and soon the 800 level will be reached.

FROZEN UP.—*Herald*, Jan. 8: The weather is moderating, much to the relief of the miners. During the past three or four days upward of a dozen mines in this district have been compelled to suspend work or in some cases to hang up their stamps. Several mines resumed work this morning. Nearly every mine in this district uses water power, and the weather has been so cold that the ditches froze from the bottom up, making it impossible to clear them in any way. All that could be done was to wait for a general thaw. In the mills the water was too cold for the concentrators, and the only thing to do was to hang up the stamps and quit.

Col. Davis of the Providence says that before another winter he will have a hot-water tank for his mill, such as is used in the Northern States. B. N. Shoecraft of the Nevada City also contemplates putting in some kind of improved heating apparatus.

BONDED A MINE.—*Union*, Jan. 16: F. W. Spencer and A. P. Hodges have secured an interest in the Comet mine, in this district, which Peter McAusland has under bond. The *Herald* says they will proceed to develop the mine at once, and men will be put to work on it to-day.

DAM WASHED AWAY.—*Telegraph*, Jan. 15: The dam in Wolf creek, just above the Granite Hill mine, was washed away under the terrible pressure of water this morning. Supt. Stephen Fowler with his men were working in water up to their waists to turn the water into the ditch in order to keep things running at the mine. The Granite Hill is all right!

TO START UP.—*Union*, Jan. 12: Superintendent Tregidgo last night informed a reporter that work would commence to-day in "pumping out" the Hudson Bay mine. When it is free of water the mine will be opened up as much as possible and several men be put to work.

SUITS COMMENCED.—*Transcript*, Jan. 15: An important suit has been commenced in the Superior Court of this county by Ed Commins, Martin Ford, et al., against Con Reilly, the Allison Ranch Mining Company, et al. The defendants have been digging a ditch to convey water to the Allison Ranch mine, which will start up again in the spring, and it appears from the complaint the defendants have been dumping debris from the ditch on to the ground of the Franklin Company, owned by plaintiffs. The suit is to restrain the defendants from continuing in their work and to recover \$1000 damages and costs.

CENTENNIAL GRAVEL.—*Enterprise*: A box of gravel from the recent new and important strike in the Centennial mine has been received by Secretary James, at the Gold Hill assay office. It is the regular old blue lead gravel of Nevada county, free washing, and pans out very satisfactorily, yielding bright, heavy gold. So far has fallen to the depth of two or three feet, preventing sluice washing for the present; but as early as possible in the spring—April or sooner—sluices will be brought effectively and lucratively to bear on the subject of future dividends.

Placer.

MINE PURCHASED.—*Grass Valley Union*: A. L. Begbie, superintendent of the Spanish mine, Nevada City, on Saturday purchased the Hathaway quartz mine in Placer county for Colgate & Co. of New York. There are 100 men employed in the mine. Mr. Begbie will continue to superintend the Spanish mine, and will also have charge of the Hathaway.

Plumas.

WORK ON A DAM.—*National Bulletin*: Work on the restraining dam to be erected across Rock creek, below the Hungarian Hill properties owned by the Plumas Imperial Mining Co., was begun Tuesday under the superintendency of F. E. Thomas, and will be pushed to completion. At the present time, not more than ten men are employed, but more may be put to work later on. Col. Day is expected to return from South Dakota in a few days, when greater activity with reference to the Plumas Imperial may be expected.

San Bernardino.

GREAT PROGRESS.—*Vanderbilt Shaft*, Jan. 12: The past week has been one in which greater progress has been made than in any other three weeks since the first location was made here. There have been, perhaps, periods of more feverish excitement over finds, and more people could be seen on the streets. Such periods have not benefited the place. The reaction that has always followed has been hurtful to Vanderbilt in the extreme. In the past week, however, much has been accomplished.

Immediately upon the arrival of his mill, and upon the arrival of Mr. Stanley and Mr. Rich, A. G. Campbell began work in earnest on the preparations for the erection of his mill. A large crew of men were put to work grading for the mill, in consequence of which the work is all done, and the foundations for the battery and engine will soon be completed. The machinery and lumber are nearly all on the ground. As soon as possible, the mill will be erected and in working order. The water for the mill will be supplied by three wells, and will flow through a 33-inch hydraulic mining pipe into a sump below the mill, from which it will be pumped as needed. This will necessitate the laying of 5000 feet of pipe.

At the Boomerang, the new steam hoist will

soon be in running order. The ore now being taken from this mine looks remarkably well. Altogether, matters are as satisfactory at Campbells as they could well be.

Things are assuming a very cheerful aspect about the property of the Vanderbilt Mining and Milling Company, also. On Monday morning the force was increased, the new men commencing the grading for the mill, which will, without doubt, arrive here by February 1st. The mill will be fitted for 20 stamps, although only 10 stamps will be put in at first. The Monday morning train brought in Mr. A. Smith of Denver, who is an able millman. He will have charge of the erection of the mill.

This week has not been without excitement. Friday night, about ten o'clock, a blast in the east drift, on the 50-foot level of the Gold Bronze, opened up a cave of crystallized quartz bearing free gold. It being remarkably rich in appearance, Mr. Saurbrey, the foreman, called Mr. Taggart down. Later Mr. Patton went also, and, as a result of the blast, the richest ore ever found here was taken out. It showed so much free gold that an excitement was raised immediately. The next morning every one looked at the rock and said it was very rich, which it was.

Shasta.

WATER SCARC.—*Democrat*, Jan. 10: The Hidden Treasure mine on Iron mountain has been compelled to hang up five stamps on account of the scarcity of water for motive power. They have discovered an immensely rich ore and put seven more men at work this week. The mine promises to become a large producer. The underground developments are a surprise to the owners.

The Minnesota-Janey & Co.—is running its ten stamps on high grade ore. It has about 200 tons piled upon the dump and in the bunkers. The output of this mine is about 40 tons a day, while the mill handles 30 tons. The concentrators are working satisfactorily.

The property being worked by Mr. Hartman near the Mad Ox mine, is showing a nice, clean four-foot vein of high grade free-milling.

Jim Hill has a fine bunch of ore on his claim at Lower Springs, and a milling test is soon to be made of 20 tons of this ore. Free gold is found disseminating all through the rock.

Messrs. Conner & Co. are pushing their development work on Salt creek, and a mill to work their ore will be in order soon.

Mining Engineer Mariansky and two Chicago gentlemen have been looking over the Quartz Hill property in Old Diggings this week. They have decided to erect a 50-stamp mill on the property at once. Old Diggings will be a busy camp this spring.

The recent test of the ores from the Bunker Hill property proved so highly satisfactory that a large plant will be erected at Middle creek in the spring for the reduction of ore on a large scale.

The bond on the John Dobelin property near Centerville expired Monday and Dobelin, after receiving several thousand dollars, again takes the property.

The property being worked by Messrs. Parsons & Co. on Orson gulch, is looking up favorably. They have sunk a shaft through sandstone and found a gravel deposit between the sand and slate. The sandstone strata was 60 feet thick. The shaft on the gravel runs on an incline of 45 degrees and has been sunk to a depth of 90 feet, where gold is being found in paying quantities. A steam pump handles the water easily and the old channel theory seems to be verified in this case.

Yuba.

MINES IN OPERATION.—*Telegraph*: At the present time Smartsville is more lively than it has been for many years. The surrounding country is well under cultivation and a large exhibit of citrus fruit and farm produce has been sent to the Midwinter Fair to let the inhabitants of this glorious State know that, although famed in the past for its minerals, it is fast coming to the front in agricultural and horticultural lines.

The Excelsior mine, which recently resumed operations under the supervision of the Debris Commissioners, has had a cleanup, and a very satisfactory one. This mine successfully restrains its debris, and it seems an outrage that it was ever closed down. The Excelsior gives employment to about 30 men at the present time.

Paddy Campbell is working his hydraulic mine, about 28 men being employed. This mine is known to be rich.

NEVADA.

Washoe District.

THE RULE DRIFT.—*Enterprise*: The drift is being pushed ahead at the rate of over 60 feet a week in the present direction, but what course will be followed after it nears the Best & Belcher north line is only known to Mr. Rule, who is confident of treating the shareholders to a surprise party before the expiration of 90 days.

SUMMARY OF COMSTOCK OPERATIONS.—The official report for the past week of Superintendent Lyman of the Consolidated California & Virginia mine says: "1650 level.—In our workings in and from the drift run north from the foot of the npraise which was carried up from sill floor of this level, we have extracted some ore of average quality. The drift running north from the crosscut run east from the drift run north from the winze (down 52 feet) has been advanced a total distance of 134 feet; face in porphyry, clay and quartz carrying a low assay value. From the drift run north from the winze (down 52 feet), at a point 126 feet north from the winze and opposite the west crosscut, an east crosscut was started and has been advanced 15 feet in porphyry, clay and quartz of low assay value. From the vicinity of the winze (down 20 feet) we have extracted ore of fair quality. We

have extracted in all during the week 72 carloads of ore—about 70 tons—averaging \$42.19 per ton, the greater portion of which came from the winze—20 feet down. The southwest drift (the Rule drift) from the 1000-foot station of the Con. California shaft has been advanced during the week 66 feet; total length, 331 feet. It has shown a softer formation, consisting in the largest proportion of quartz which carries an assay value of \$2 to \$6 per ton; the face is in porphyry, clay and quartz averaging from \$2 to \$4 per ton."

The official report from the Best & Belcher mine is as follows: "200 level.—The north drift which was started in west crosscut No. 3, 175 feet from the main north drift, has been extended 15 feet, passing through porphyry and quartz showing some value; total length, 108 feet. 900 level.—The east crosscut on the north line has been advanced 20 feet; total length, 273 feet; face in porphyry."

Following is a summary of the official news from the other Comstock mines: In the Ophir, on the 1465 level, the north drift from the west crosscut is in 54 feet, the face being in a porphyry formation. Have commenced repairing the Central tunnel for the purpose of prospecting therefrom when the repairs are completed. In the Mexican the west crosscut from the south drift from the top of the npraise, 45 feet above the 1465 level, is in 21 feet, the face being in porphyry and clay. On the 900 level of the Union Shaft the joint Union Con. and Sierra Nevada north drift from the west drift is in 360 feet, and the face is in hard porphyry. On Cedar Hill the Sierra Nevada intermediate south drift is in 364 feet. The face is in porphyry. On the 420 level of this A. Des the north drift from the west crosscut was advanced 9 feet, continuing in ore of good assay value.

In the Hale & Norcross mine they continue to stop ore from the winzes below the 1300 level, and extracted during the week 16 cars of ore, assaying \$47.07 per ton per car sample, and five cars of ore, average assay per car sample \$20.31 per ton. In the Chollar mine they are making repairs in main shaft below 850 level. Extracted and sent to the mill the past week 132 tons of ore from the 100 level. Milled during the week, 150 tons. On hand at mill, 94 tons. Average battery assays, \$22.39; average car-sample assays, \$27.95. In the Potosi mine the east crosscut, 300 feet south of north line, 750 level, is out 56 feet; face in soft porphyry. During the week have been making repairs on the 250, 450 and 930 levels. On the 820-foot level of the Ward shaft the west drift from the station is out 445 feet from the shaft; face in porphyry. Repairs to the old Alpha shaft are still being made. In the Kautuck Con. mine, on the 1100 level, the south drift in the east ledge is in 47 feet; face in low-grade ore. The npraise from the west crosscut is up 40 feet; top in fair-grade ore. In the Occidental mine they continue to extract from the west ledge above the 400 level 8 tons of ore per week of the average assay value of \$44 per ton. The west crosscut from 2 npraise, started at a point 75 feet below the 300 level, is now in 186 feet, and continues in porphyry with seams of quartz.

IDAHO.

WHY THE MINES CLOSE.—A Wallace special, Jan. 8th, says: The increasing cold weather of the past few days has temporarily shut down the Union and Frisco concentrators, throwing 50 to 75 men out of employment for the time being.

The Tiger mine at Burke shut down Saturday. At the time of the shut down 85 men found employment there. There are now 23 men working under contract, and about seven or eight will be employed in addition, so that the cessation of work is not absolute, but at least one-third of the working force of the mine will be retained. F. R. Culbertson, the superintendent of the mine, said: "We are shutting the mine down simply because we cannot make any money at the present prices of lead and silver, coupled with the increased expenses incident to the winter season. We have shut down until such a time as there is an improvement in the prices of the metals or a reduction in the working expenses."

BOUGHT A MINE.—The Flannigan gold mine, located six miles from Boise, has been sold to Portland parties represented by Harry Raymond. The price is not made public. The property is believed to be valuable. It is the intention of the purchasers to put on a Crawford mill at once and it is understood that if it proves successful a more extensive plant will be put in to handle the ore, similar to those of the Flannigan mines.

OREGON.

NEW MILL.—*Jacksonville Times*, Jan. 11: A new five-stamp mill is expected soon for the Shorty mining claim in Ashland district. The mill-site is on Bear gulch, within 200 feet of the present dump. The mine has been paying under rather adverse circumstances, as the ore has been hauled several miles by wagon to be milled.

MACHINERY EN ROUTE.—*Baker City Democrat*, Jan. 8: Mr. O. B. Hardy, the lessee and manager of the Phoenix mine, who is in the city, has received word from the East of the shipment of a carload of machinery for the mill plant now in course of erection at the Phoenix, and Mr. Hardy expects its arrival in Baker City in a few days, at which time the machinery will be forwarded by rail and team to the mine. Mr. Hardy expects the mill, a ten-stamp, in operation on the mine by February 1st or thereabouts. The latest reports received from the Phoenix are of a very encouraging nature, and Mr. Hardy is in the best of spirits over his flattering prospects.

STEKE AT SPAETA.—*Baker City Democrat*, Jan. 8: Senator Wright arrived from Sparta by last evening's stage and brings the reliable news that in the Ollie Woodman mine an ore body

has been exposed at a depth of 120 feet which is four feet wide and will average \$100 in gold to the ton.

BIG MINING DEAL.—*Jacksonville Times*: J. M. Sparham & Co., mining brokers of Seattle, Wash., have purchased 600 acres of mining ground in Footh Creek district. This includes all of what is known as the "Old Cement Channel," and is supposed to be very rich. The land was owned by Messrs. Baily, McKnight, Goldworthy, Swacker and Brooks. The parties have executed a deed in trust to the company, conditioned that if the purchase price is not paid on or before June 28th the land reverts to the original owners. Sparham & Co., who have plenty of means, intend to thoroughly prospect the ground.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

- FOR THE WEEK ENDING JAN. 2, 1894.
- 512,089.—DEMINATING MACHINE—Fred Baugert, S. F.
511,995.—WATER PURIFIER—C. F. Buckley, S. F.
511,933.—BOX FASTENER—W. T. Collier, Los Angeles, Cal.
512,161.—STREET SWEEPER—M. Crawford, Jr., Stockton, Cal.
511,983.—TELEPHONE ROOSTER—A. R. Duperré, S. F.
511,940.—PISTON—M. W. Fairbanks, Boonville, Cal.
511,942.—INSOLV.—W. W. Glavin, S. F.
512,021.—WAITING METALLIC SHEETS—J. Gould, Jr., Oakland, Cal.
511,952.—CAR PUMPER—J. Hubash, S. F.
512,110.—SULKY HARROW—T. J. Hubbell, Santa Cruz, Cal.
511,954.—STEAM ENGINE—B. Jackson, S. F.
511,934.—DISPLAY CASE—John Kahn, Los Angeles, Cal.
511,902.—WICK TRIMMER—J. W. Lawson, San Bernardino, Cal.
511,985.—CAR OPENER—T. B. Lepley, La Grande, Or.
512,043.—PIANO—H. Miller, Stockton, Cal.
512,253.—HOISTING MACHINE—G. C. Murray, Seattle, Wash.
511,966.—HAIR CLIPPER—O. Olsen, Oakland, Cal.
511,968.—STEAM BOILER—D. Risley, Colfax, Wash.
512,233.—BRACE—F. M. Speece, S. F.
512,063.—CAR COUPLING—C. B. & T. D. Stewart, Walla Walla, Wash.
511,977.—SEWING MACHINE—Mary Tobener, Gold Hill, Nev.
- FOR THE WEEK ENDING JAN. 9, 1894.
- 512,593.—GATE—J. W. Bennett, Woodford, Cal.
512,269.—SHIP'S LOG—F. A. Ebbop, S. F.
512,600.—SAWING MACHINE—F. D. Butzer, Cosmopolis, Wash.
512,431.—VENEERING STONE—Chatain & Giletti, S. F.
512,543.—MOP HEAD—R. Froberg, S. F.
512,237.—BEST HARVESTER—W. K. Gird, Chico, Cal.
512,440.—VAULT COVER—H. Hauslein, S. F.
512,294.—GATE—Hopkins & Simons, Blalock, Or.
512,616.—WINE PRESS—Jas. Kelly, S. F.
512,659.—CARPET TACKER—D. H. McFalls, Ellensburg, Wash.
512,652.—INK PUMP—O. M. Moore, Huguana, Wash.
512,447.—TYPE HOLDER—A. E. Newby, San Jose, Cal.
512,624.—WINDOW SHADE—Z. Phinard, Portland, Or.
512,662.—MOLD—E. L. Ransome, Oakland, Cal.
512,663.—CONCRETE MIXER—E. L. Ransome, Oakland, Cal.
512,685.—TARLER—G. K. Russell, San Diego, Cal.
512,439.—LIQUID AGITATOR, ETC.—A. H. & T. A. Schluster, Oakland, Cal.
512,454.—TELEPHONE TIME INDICATOR—C. Stever, San Jose, Cal.
512,411.—ENGINE GOVERNOR—I. F. Thompson, S. F.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

APPARATUS FOR AGITATING AND DISCHARGING LIQUIDS.—A. H. and T. A. Schluster, Oakland, Cal. No. 512,489. Dated January 9, 1894. The object of this invention is to provide an apparatus which is especially designed for containing milk or other liquids, the constituents of which are inclined to separate from each other when the liquid remains for a considerable time in a quiescent state, as in the case of cream rising on the surface of the milk, and to keep the liquid agitated so as to prevent such separation, to protect the surface from dust or from atmospheric influences, and to provide a convenient means for drawing off the liquid from time to time and simultaneously agitating it. In carrying out this invention, an exterior chamber is employed having an interior fitting within it, the outer chamber being open at the top while the inner one is open at the bottom and closed at the top, and has an opening made with a screw cap to close it. A filling passage is made upon one side of this chamber, and a discharge cock is fixed in one side of the outer chamber. The barrel of the cock is so curved as to cause a siphonic action when it is open, and as the liquid flows out through this cock air is drawn in through the filling passage, and, rising up through the liquid in bubbles, keeps it constantly agitated.

MOP HEAD.—Richard Froberg, S. F. No. 512,543. This invention consists of a mop-head having a transverse jaw with a socket by which it is secured to the handle and sharp-pointed spurs projecting from the face of the jaw. In conjunction with this, and hinged to a bracket at one end of this transverse bar, is an opposing bar having pointed spurs projecting so as to interlock with those of the first bar when the second one is closed. The second bar has a spring actuated locking device at the end which holds it fast when closed, but it is easily unclamped to allow the parts of the head to be separated and the old material removed and new introduced when necessary.

MANUFACTURE OF ARTIFICIAL GRANITE AND VENEERING STONE.—E. Chatain and S. Giletti, S. F. No. 512,431. This invention relates to the manufacture of artificial granite and veneer-

ing stone. It consists in first tamping a layer of the body forming material in a mold, one inner vertical wall of which is formed by a vertically movable slide, then removing the slide and tamping a layer of the facing material in the space formed by the lower end of the slide, then replacing the slide with its lower end resting on the tamped facing layer, and tamping the second body forming layer and again removing the slide and tamping the second facing layer, thus continuing the formation of the body and facing material by successive steps until the face block of the desired thickness has been provided. This enables the manufacturer to make a body forming material of cheap substances and a facing of more expensive material which will show any kind of finish desired, the two being united while in a plastic condition so that the block becomes essentially homogeneous when it is set.

ENGINE GOVERNOR.—I. F. Thompson, San Francisco, Cal., assignor of one-half to W. L. Palmer, No. 512,411. Dated Jan. 9, 1894. This invention relates to a differential spring governor for steam engines, which is applicable either to control a valve by which steam is admitted to the engine valve chambers or to directly actuate the cut-off mechanism of any well-known type of valve. It consists of a fulcrum lever, one arm of which connects it with the valve or cut-off stem and the other with a collar sliding upon the governor spindle. The governor balls or weights have short arms connecting with a bar fixed to and rotating with the spindle, and other arms extending outwardly on the opposite side and connecting with the bar which is slidable upon the spindle and which actuates the movable collar. The angle formed by the levers which extend out from the opposite side of the balls or weights are internal angles, so that as the balls are thrown outward, these balls are brought more nearly into a straight line with each other. A compression spring acts to return the parts when the centrifugal force is reduced.

TIME INDICATOR ATTACHMENT FOR TELEPHONES.—Cbas. Stever, San Jose, Cal. No. 512,454. This invention consists of an indicator electrically connected with a telephone and provided with a mechanism which is set in operation by the connection of two telephones whereby a response is returned over the telephone wire, the object being to provide for an automatic response from the telephone which is called during the absence of the occupant of the office. The indicator is set for the time at which the operator will return to the office and remains normally inactive, but when the telephone to which the indicator is attached is connected through the central office and the distant subscriber calls, the indicator is set in operation and makes a response which indicates the absence of the person and the time at which he will return.

HOLDER PLATE FOR TYPE.—A. E. Newby, San Jose, Cal. No. 512,447. This invention relates to that class of holders for receiving and confining several independent parts, such as letters, dies, designs, cuts and other characters, but it is especially intended for the holding of removable and interchangeable type whereby they may be combined in various relative positions as desired. The invention consists essentially of a peculiarly constructed bed-plate, with an overlying clamping frame adapted to hold the type or other characters to the bed-plate, and its use saves the time and expense of separate dies for each mark or label to be printed.

THE ORIENTAL GAS ENGINE

IS THE BEST, because it combines simplicity of construction with power and economy in space. It can be run with natural or manufactured gas or gasoline at a cost of 20 to 25 cents per horse power per day.

It can be used for pumping purposes, as well as for all purposes where a perfect engine is required, with the advantage of lessening the risk of explosion. No licensed engineer at a high salary needed to operate it. Send for circular and prices if a good safe engine is what you need.

The Oriental Launch is Perfection.
M. A. GRAHAM,
Inventor and Manufacturer,
105 BEAL STREET, SAN FRANCISCO.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, \$6.00, post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.
The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Market Reports.

The Markets.

SAN FRANCISCO, Jan. 18, 1894.

The silver market during the week has shown practically no change. Lead, notwithstanding the falling off in production, has shown no improvement. The tariff agitation seems to be the main depressing influence. Copper has been weaker. James Lewis & Sons, London, in their circular Jan. 2, say: "Nearly all the contracts for refined copper at low prices, made by American producers and smelters for delivery during 1893, are now completed. The future of values now mainly depends upon whether time will be given for the absorption by consumers of the large supplies sent to the Continent—chiefly to Germany, those to England and France being already well absorbed."

NEW YORK, Jan. 18.—Following are the closing prices for the week:

	Silver in	Copper	Lead	Tin.
Thursday	68 1/2	10 1/2	3 10	20 50
Friday	68 1/2	10 00	3 10	20 20

Mining Share Market.

SAN FRANCISCO, Jan. 18, 1894.

The Comstock market was subject to small fluctuations during the past week, but business was fairly remunerative to the commission brokers.

Monday's business opened dull. Tuesday, Consolidated California & Virginia sold as low as \$3.20, Best & Belcher \$1.90 and Ophir \$1.40, with a smaller cut in the prices of the other stocks. The direct wires to Virginia City prostrated by Sunday's storm were not in working order, but dispatches were received by way of Reno, Helena and Portland, with less than an hour's delay in transmission, and brokers who have agencies on the Comstock were active sellers for a time. At 10:30 A. M. a sharp break in prices caused many purchases to be made for account of dealers who were short on the market, and this imparted a steadier tone to the market, and prices had a small recovery.

Advices received Tuesday reported the southwest or "Rule" drift on the 1000-foot level of the Consolidated California & Virginia mine to be about 370 feet from the station of the old Con. Virginia shaft, with the face in a soft formation composed of porphyry, clay and streaks of quartz.

The market closed in a weak condition Tuesday afternoon, with sales of Con. California and Virginia at \$3.25, Best & Belcher at \$1.90, Ophir at \$1.40, and prices 5 and 10 cents lower for most of the others as compared with what they sold at on the regular session. There was an active volume of sales, Wednesday morning the market opened much duller, but prices were slightly steadier under a demand for cash stock from Pacific Board traders who sold short yesterday and had to make deliveries before noon to-day. The regular wires to Virginia City were up and working well Wednesday morning, but they brought no news of any changes in the condition of the mines. To-day there are no changes of note.

California and Colorado.

California easily maintained its lead during 1893 as the chief gold-producer of the United States. It might appear from the figures of Wells, Fargo & Co., printed in the Press last week, that Colorado is a close second, and perhaps in time destined to pass the present leader. But it is not at all probable that the Golden State will lose its prestige. The figures given for the two States by Wells, Fargo & Co. are as follows:

California—Gold dust and bullion by express, \$9,697,036; gold dust and bullion by other conveyances, \$1,475,000; silver bullion by express, \$257,005; ores and base bullion by freight, \$1,667,907; total, \$13,096,948.

Colorado—Gold dust and bullion by express, \$7,229,643; silver bullion by express, \$16,369,257; ores and base bullion by freight, \$3,878,635; total, \$27,477,535.

It is fair to say that practically the whole output of California, represented in the above figures, is gold, except the \$257,005 silver. The item "ores and base bullion by freight" was made up of sulphurets and highly sulphuretted ores forwarded to Selby's and other smelters for treatment. In the silver States, however, this item contains little gold, but is made up of silver-lead ores, argentiferous copper ores containing gold and silver, lead ores proper and high-grade silver ores. The Colorado gold output, therefore, is fully represented by the statement that its output was \$7,229,643, while all in California is gold except the one silver item of \$257,005. The California output is then, according to Wells-Fargo's estimates, \$12,839,943.

It is to be borne in mind also that the Wells-Fargo estimates in this State are below the Mint estimate; while for Colorado they are quite equal. It is not necessary here to explain the reasons. It is by no means certain either that the system of allotment of returns to the various States and Territories is exact and that Colorado has not received more than its share. Probably it has. It is well known that ores from all over the coast are shipped to the great smelters of Colorado. Some of the smelters keep their returns by States and Territories; some do not. It is therefore not possible always to state what ores belong to Colorado and what do not.

Colorado made an excellent showing in 1893 considering all the circumstances; but, as a gold producer, it is yet several laps behind California.

THE House Ways and Means Committee some time ago added a proviso to that portion of the free list concerning petroleum, imposing a present duty upon all oil imported from countries which impose a duty on our product. The Democrats of the Ways and Means Committee, on Wednesday, agreed to strike this off and put petroleum on the free

list, claiming that the opposition to it had been worked up by the Standard Oil Company. Representatives of the oil interests at Washington are fighting it on the ground that it is done in the interests of the Peruvian oil producers and assert that a line of tank steamers is being built to carry Peruvian oil to San Francisco, and that contracts have been made to deliver oil in San Francisco at 75 cents per barrel less than the present price. They state that

WALL'S IMPROVED CRUSHING ROLLS.

this change has been made in the interest of J. W. Grace & Co., of which firm ex-Mayor Grace of New York, leader of the "Anti-Snapper" convention, is a partner.

MONTANA will have a very interesting exhibit at the Midwinter Fair. Two carloads of ores and gems are on

THE WALL SHELLS.

their way here. Conspicuous features will be rubies and sapphires, the Ada Rehan silver statue, gold, silver and copper ores. It is designed to show copper in every stage of its development, from the time it leaves the mines until it is cast into bars. Montana is the greatest copper State in the Union, and this feature of the exhibit will doubtless be valuable.

The Wall Improved Crushing Rolls.

The Wall rolls differ from the "Cornish" and other roller crushers in common use, chiefly in the novel construction and arrangement of the crushing faces, which consist of series of parallel corrugations, extending across the face of the shells, either parallel or inclined to their axis, the corrugations being rounded or curved with such

proportions that, when intermeshed and rotated, every portion of the surface of each will press equally upon the counterparts of the opposite roller; and, being held firmly in position by suitable steel gear, slipping of the crushing faces upon each other or upon the material being crushed is said to be rendered impossible.

By reference to the smaller illustration, it will be seen that the meeting or crushing faces present at all times overlapping curved surfaces, between which the material is firmly held, and crushed by almost direct pressure, thus avoiding "grinding" or uneven and rapid wear of the face of the shell, and the consequent destruction of the ores by the production of refractory "slimes." This feature renders the crusher of value for the preparation of ores for concentration or lixiviation and in the crushing of high-grade ores and matte for sampling or transportation.

One of the crushers placed to receive and crush the product of the rock-breaker in the common stamp mill, it is claimed, will add 20 per cent to the capacity of

a battery of 60 stamps. The Parke & Lacy Co. are agents.

AFTER 27 years of continuous litigation the famous land title case of Isaac E. Davis and Henry Cowell against the California Powder Company has reached an end. This information was conveyed to the interested parties in this city by recent telegrams from Washington announcing that the Supreme Court had virtually decided in favor of Henry Cowell, the surviving plaintiff. The decision involves the title to several hundred acres of land on the east bank of the San Lorenzo river, in Santa Cruz county. Its chief value to the powder company lay in the fact that it adjoined their other property.

THE River Improvement delegation of six has already gone to Washington. If hoards of county supervisors can see their way clear to pay a large part of their expenses, there is no good reason why like contributions cannot be made for the miners' delegation.

THE Virginia City Enterprise declares that the Congressional "act suspending hydraulic mining is now conceded to have been the most unjust ever passed by Congress." Congress has a good deal to answer for, but it did not promulgate the Sawyer decision.

Lower Wages in Future.

The claim is advanced by mine-owners in the silver regions that if wages had been \$2.50 to \$3 per day instead of \$3.50 and \$4, many of the idle mines would now be running, and the calamities which overwhelmed the industry in a great measure avoided. This is, of course, one of the big "ifs" that cannot be removed from the past history of the mines. The claim may or may not be well founded. But it is inevitable that reduction of wages occur in the future. Hard times are an irresistible weakening force, and, in our opinion, miners' unions will not be so well able to maintain wages as in the past. It is comparatively easy for the skilled laborer to dictate the terms of his employment when times are good, when mines are prosperous, and when a cessation of operations through labor or other troubles is a disaster an employer will ordinarily do much to avoid. But when an industry is prostrated; when the workmen must have bread, and when there are ten applications to one vacancy, the mine-owner can, within certain limits, pay what he pleases. At the present the necessities of the silver mine operators compel economical administration in all branches; the necessities of the miners will drive them to seek employment at almost any figure. It will not be very difficult under these circumstances for employer and employee to find a basis of mutual understanding. It will be found that a mine here and there is paying less than the scale, and then the miners will either themselves voluntarily reduce the scale, or it will come down by force of circumstances. Of course we do not expect to see a reduction in California.

It is not intended by these statements to advocate either reduction of wages or retention at the present rate, but simply to point out the situation and the certain result. There is scarcely a branch of industry in which less wages are not now paid than two years ago, and there is no reason why silver mining shall prove an exception to the rule.

It is desired by the California Miners' Association to raise a sum of money sufficient to send to Washington two delegates whose mission it shall be to explain to and urge upon Congress the association bill for the regulation of mining; and, likewise, to secure an appropriation for the construction of a restraining dam or dams in accordance with the recommendation of government engineers. For the latter purpose, it will be remembered, the State has already made a contingent appropriation of \$250,000. The funds of the Miners' Association are low, and it will be necessary to call on friends of the movement. Various boards of county supervisors have been asked for an appropriation of \$300 each (Nevada for \$500), and it is to be hoped they will respond promptly. The importance to

California of the measures which the delegation shall urge are very fully appreciated, and it ought to be necessary only to mention that the money is needed to call forth a ready and generous response from all interested.

The Quicksilver Tariff.

The Wilson tariff bill proposes to remove the specific duty of ten cents per pound on quicksilver and place it on the free list. Probably no single industry in California is more deeply concerned in the maintenance of adequate protection, or will be more seriously injured if brought directly in competition with the foreign product. It is well known that practically all the quicksilver of the United States is produced in this State; that the total investment of capital is in the neighborhood of \$30,000,000; that several thousand laborers are dependent upon the industry for a livelihood; that great difficulties of a permanent nature are encountered in the operation of the mines; that little or no profit is now being returned to the owners; that the deposits are slowly being exhausted; that no new deposits yet uncovered have become large producers, and that the home product is in excess of the home consumption. On the other hand, the foreign output is double that of California, the deposits are enormously rich and the reserves heavy. Their control is in the hands of a great syndicate that regulates the output to suit the condition of the market, and the American markets, if thrown open, would be absolutely at the mercy of one great monopoly, the Rothschild syndicate, which controls the mines of Spain.

The conditions of quicksilver production are so unusual, and their disadvantages in this country so conspicuous, that it is very easy to point out the effect of a tariff policy which withdraws protection from an industry which barely thrives under present circumstances. The duty on quicksilver now amounts to \$7.65 per flask. It is absolutely the only influence which preserves the Eastern markets to the home product, and, not counting less freight rates, it is the only influence which preserves the Western market; in other words, it is not possible for the California article to pay freight across the continent and compete on the Atlantic seaboard on equal terms with the Spanish or Austrian product, and it is possible for the foreign article, if unrestricted by tariff duty, to supply the mines of the West and drive the California quicksilver from the field, simply because the cost of production is much cheaper. Why the cost of production is less we will show briefly:

The cinnabar deposit at Almaden (Spain) is the most perfect known. It consists of three parallel veins and fissures, about 100 feet equidistant, growing richer and wider as penetrated. The average percentage of metal per ton of ore is about ten per cent. It is necessary to raise from the mine only a very small per cent of waste (perhaps two or three per cent). Wages are (or were recently) as follows: Miners, ore chambers, 81 cents per day of six hours; masons, in quarries, \$1.03; timbermen, 55 cents; furnace men, 40 cents.

In California the deposits are persistently irregular. The average percentage of metal per ton of ore at the New Almaden is one per cent or less. The quantity of waste to be removed is very large. Unwearied prospecting is necessary. The wages in California averaged one year recently for all employees \$2.43 a day. Average number employed, 425; average time worked in the year, 290 days. At the smelting works the average earnings per day were about \$2.30.

In 1833-84 (an average year), the total amount of material taken from the mine was: From ore chambers, 17,575 tons; from barren ground, 1900 tons. Of the ore raised 17,101 tons were worked only, 456 tons being worthless. Tons of ore reduced, 18,465.57, yielding 45,765 flasks, or 9.485 per cent. The quantity of ore handled in the year to each worker was only 6.23 tons, while at New Almaden in all the mining departments there were only 425 persons employed for the extraction of 138,640 tons, or an average of 326 tons a year to each worker, more than fifty-two times as much per year as at Old Almaden.

The following tables are from official sources and are very instructive. The first shows the relative mining cost per ton of material (productive and non-productive) extracted from mines:

	Almaden, Spain.	New Almaden, California.
Excavations.....	\$3 60.3	\$1 63.6
Strengthening.....	1 42.4	15.8
Drainage.....	0 16.6	04
Lowering, hoisting and tramming.....	36.8	23.2
Surface.....	14.3	10.2
Management of machines.....	02.6	04
General expenses.....	1 50.4	15.4
Workshops.....	25.5	04.2
Supplies.....	\$7 30.9	\$2 45.4
	1 21.6	90.2
	\$8 52.4	\$3 35.6

The following table shows the cost of quicksilver per

flask, from the average for one year at Almaden, Spain, and New Almaden, California (1835):

	1833, Almaden.	1835, New Almaden.
Staff and office expenses.....	\$0 75	\$0 80.6
Excavations—mine expenses.....	1 62	10 47.6
Strengthening " ".....	06	99.6
Drainage.....	01	25.2
Tramming " ".....	29	1 57
General expenses.....	70	1 84.3
Supplies.....	56	5 75.5
Distillation and flasking quicksilver.....	1 92	3 49.9
Workshops.....	12	45.2
Sundry expenses.....	23
Hospital and Chapel.....	07
Pasture of Castles.....	07
Unforeseen expenses.....	03
Transportation by teams.....	75.7
Totals.....	\$7 10	\$26 38.6

These figures show that in 1835 eight times the amount of material was extracted from the American mine than was taken from the Spanish mine in 1833, its production, however, averaging only 20 pounds of quicksilver per ton for that year, while the Spanish mine's production was 200 pounds per ton; that the average number of tons handled for each worker in the Spanish mine was only 6.23 tons, while at the American mine there was extracted over 63 tons per worker, or ten times the amount extracted in equal time; that the cost of production of the Spanish mine was 27-100 of that of the American mine. It costs no more to extract and reduce rich ore than poor, and were the American ores equal in richness to the Spanish, the production of the American mines would be ten times as great, and cost \$2.64 per flask.

It is true that production of quicksilver in California has greatly decreased; but consumption—owing to paralysis of the silver industry—has likewise fallen off, and the demand does not equal the supply. Prudent and economical methods and skillful management alone make it possible for the mines of California to be operated under present conditions. If their difficulties are aggravated by unwise tariff legislation there is but one thing to do, and that is to shut down. There can be no reasonable doubt that, when once idle, the American market will be in control of the Rothschilds syndicate, and the price will be fixed at its pleasure.

Twenty-Four Out of Forty.

Of the forty applications made to the Debris Commission, twenty-four have been passed on favorably. That is to say, twelve licenses have been granted, and, in addition, twelve sets of plans for that number of mines have been approved. This is a definite pledge by the Commission that as soon as the impounding works are erected in accordance with the plans, formal license will be granted. Of the remaining sixteen out of the total of forty, ten have just been advertised, or are being advertised, and are in process of consideration; three mines have not yet been visited because of inaccessibility, and three are awaiting further information.

The Press published, two weeks ago, a list of all the applications made to the Debris Commission, with licenses granted. In addition to the twelve licenses granted, the plans of the following twelve mines have been approved, and the Commission is awaiting construction of the necessary works, when license shall be granted:

Kelly Hill mine, Butte county.
 Omega mine, Nevada county.
 Brandy City mine, Sierra county.
 Illinois mine, Plumas county.
 Eureka mine, Sierra county.
 Craycroft mine, Sierra county.
 Excelsior mine, Sierra county.
 Spanish Ranch mine, Plumas county.
 Denmore mine, Sierra county.
 54 Flat mine, Amador county.
 Red Hill mine, Shasta county.
 Walker mine, Shasta county.

Of these the Kelly Hill, Omega, Brandy City, Illinois and Spanish Ranch are mines of large capacity. Work is progressing on the dams of most of these, and on others construction awaits a more favorable season. So far as known, none have found that they cannot construct dams on the lines required by the Commission.

Foundry Notes.

THE Fulton Iron & Shipbuilding Works are about to issue a new catalogue. The first 32 pages will be printed this week.

THE Fulton Iron & Shipbuilding Works have just shipped a lot of mill supplies—shoes, dies, etc.—to four different mines in Mexico. "The Mexican trade is the liveliest branch in business just at present," said Mr. James Spiers. "Mining operations in Mexico are comparatively active, and we are getting our full share of the business."

THE Parke & Lacy Company have just made the following shipments: To the Utica mine, Angels, Calaveras county, one Ingersoll-Sergeant piston-inlet belt and geared duplex compressor, seven-drill capacity; to C. Staacke, Mexico, one Ingersoll-Sergeant piston-inlet single compressor, seven-drill capacity; to Pine Hill Milling & Mining Company, one single compressor, three-drill capacity; to Enreka Machine Works, San Francisco, one Lodge-Davis lathe and shaper; to Oakland, Alameda & Piedmont electric road, Fifield lathe; to White Star Laundry, Oakland, engine and boiler.

The Future of Gold and Silver.*

By S. F. Emmons, of the U. S. Geological Survey.

In reviewing the production of the whole country for the period under consideration (since 1880), it is to be remarked that the gold product has remained fairly steady while the silver product has nearly doubled. The average gold product of the country since 1873, as shown by available statistics, has been about \$33,000,000 per annum, except during the years when the Comstock mines were in bonanza, in the abnormal yield of which it is fair to assume the increased product during the years 1876-1880 was due. The falling off during the first half of the last decade was due to the restriction of hydraulic mining, which in the later years has been replaced by the normal increase from deep mines. It is probable that the increase for 1892 over former years is greater than present statistics show. On the whole, the gold industry may be said to be in a normal and healthy state, ready for a permanent though not necessarily rapid increase, as more capital is intelligently directed to its development.

The increase in the silver product has been phenomenal, especially when it is considered that the yield of the Comstock lode, which during the previous decade constituted about half the total product of the country, has become practically an insignificant factor, and that the average price of the metal itself has steadily fallen during the period, except for the few months immediately succeeding the passage of the Sherman Act; the average price for 1892 having been about 25 per cent less than that of 1880.

The prime factors in this increase have been the discovery and development of great ore bodies in limestone, such as those of Leadville and Aspen, the ores of which must be reduced by smelting. This has resulted in the building up of the great smelting industry in the West and, in consequence, of an immense increase of railroad facilities, which in turn have encouraged the investment of capital in other mining enterprises. The development of the great veins of Utah, Montana, and the San Juan region, although they produce ores not necessarily reduced by smelting, is nevertheless dependent upon railroad facilities which the smelting industry has been the most important factor in developing. In other words, the increase in the silver industry has been due mainly to favorable industrial conditions. If capital had not been invested in railroads and reduction plants, mining would have been confined to the richer ores near the surface, and would probably have been abandoned when these were exhausted; for it has been handicapped during the entire period by the abnormal figures at which the miners' unions have been able to keep the rate of wages, while they have been reduced in almost every other branch of industry.

That the industry as a whole has progressed in spite of a continuous fall in the value of the product has been mainly due to the fact that the larger reduction works, under the spur of the necessity of rendering the large capital invested in their plants productive, have displayed ingenuity and economy in improving their processes and in reducing the cost of fuel and other materials, so as to leave them still a margin of profit. The smaller profit is offset in the case of the larger smelters by the greater number of tons treated, and also by the utilization of other products besides the precious metals, such as lead and copper. As long, therefore, as these larger smelters can obtain even a very small profit, silver mining will be continued in the larger mines and in those whose ore is exceptionally high grade, while the smaller and less favorably situated mines will gradually be abandoned. It is to be assumed, moreover, that self-interest will induce the miners to consent to a reduction in wages when it becomes a question of that or nothing, and thus a still longer lease of life will be given to some established mines in the face of a continuous reduction in the price of silver; but when this price shall have fallen so far, without a counterbalancing rise in the price of lead and copper, that the larger smelting works are obliged to close, silver mining will be abandoned throughout the greater part of the Western region. This exigency is not, however, likely to occur while the price fluctuates, as it has done during the past year (1892) between 70 and 80 cents per ounce. †

Assuming that silver continues at about these prices, it is probable that the greater part of the silver product of the country will come from Colorado, Montana, Utah, Idaho, Nevada, New Mexico and Arizona, in the order named, and will gradually be reduced to between thirty and forty millions annually.

The annual gold product, on the other hand, is likely

to see a steady increase to \$40,000,000, and perhaps beyond, and its principal producers will be the following States and Territories, also in the order named: California, Colorado, Dakota, Montana, Idaho, Oregon, Alaska, Arizona, with a great deal of uncertainty as to the relative rank of the smaller producers.

An industry is of value to the country at large in proportion to its permanence and absence from violent fluctuations, and the silver-mining industry has been in this sense of great value. The large amount of capital invested in extensive plants and tributary railroads has given profitable employment to great numbers of people, and assured greater permanence than the many small gold mines and gold-reducing plants. Its destruction would therefore constitute a serious loss to the nation's industry. It may fairly be doubted, however, whether the course followed by the friends of this industry has been the wisest that could have been pursued, and it seems probable that if no attempt had been made to sustain the price of the metal by legislation, but it had been left to follow the natural course of trade, under the laws of supply and demand which govern the production of other commodities, it would to-day be in a more healthy condition. While its growth and increase of product would have been less rapid, those engaged in it would have been better able to forecast the future course of the price of silver, and would have regulated their investments accordingly.

The recent overproduction of silver, relatively to that of gold, which has led to an attempt to establish the world's coinage on a purely gold standard, is, however, the result of a normal, and, for the most part, healthy development of industrial conditions over a long series of years.

That these conditions are at present abnormally disturbed, and that those engaged in the silver industry find themselves in danger of great pecuniary loss, is apparently due in large measure to effects produced upon the price of the metal by legislative action. If the natural law of supply and demand be allowed to act freely, and if no attempt be made to control by legislative enactment the ratio between gold and silver, the variations will be less violent and less injurious to the industrial interests based upon silver mining.

The world's product of silver for the five years from 1880 to 1884 was on the average about equal in coinage value to that of gold. From 1885 to 1891 it has steadily increased, reaching \$185,000,000 in the latter year.

It still remains to consider what is likely to be the product of the precious metals throughout the world during the balance of the present decade from the point of view of the geologist and miner, as contrasted with that of the legislator and financier. From this point of view the most uncertain regions are Asia and Africa for gold, Australia and South America for silver.

The gold product of the United States is likely to show, as has already been stated, a moderate and steady increase. That of Australia is at any rate not likely to decline. In Asiatic Russia, which is said to have shown an increase of 9 to 16 per cent in late years, the product is likely to increase still more with the progress of the trans-Siberian railway now building. This region undoubtedly possesses great mineral wealth, and the gold deposits, whether placers or deep mines, are likely to be first developed. The most important increase in the gold production will, however, come from South Africa; and what is still more important, this increase will be of a more gradual and permanent character than that derived from California and Australia thirty years since, inasmuch as it will come from deep mines and not from placers. The greater part of the present production is obtained from a conglomerate belt, not unlike in its geological relations to the conglomerate belt from which the copper of the famous Calumet and Hecla mine is derived, and which is considered by some observers to be an old placer deposit like that of the Black Hills of Dakota. Recent borings have proved that this African conglomerate belt continues to be rich in gold at a depth of between 2000 and 3000 feet, thus assuring the permanence of its production for many years to come, and justifying the expenditure of capital in its development to an extent that may make its annual product very large. It is, therefore, quite fair to assume as a reasonable probability that the gold production of the world may increase to \$150,000,000 within a few years, and possibly to \$200,000,000 before the close of the decade.

Silver, which has the disadvantage in respect to gold of being too bulky for actual use as a medium of exchange in large sums, besides being in other respects naturally an inferior metal, is practically valued on a gold standard in all matters of international exchange, whatever value may be given to it within the borders of an individual nation by legislative agreement. The reduction of silver from its ores, as has already been stated, being so complicated a process, silver mining is far more dependent on favorable industrial conditions than gold, and its future development is hence dependent on its gold price. That there

still exist, if not in the United States which is probably the most thoroughly prospected country, at least in some part of the world, great bonanzas of silver, comparable in value to the famous Comstock lode, is not to be doubted; but with a low price of the metal they will be less diligently sought after, and even if discovered capital will be more reluctant to invest in them.

If no attempt be made to control by legislative action the commercial course of silver as a metal, its production will doubtless be governed by the same conditions that have applied to copper in the past twenty years, a metal with which it presents many analogies, both in geological relations and physical characteristics. When the production of copper became greater than the ordinary demands as commerce, its price decreased until only a few of the larger and more favorably situated mines could produce it at a profit. These mines were not necessarily the richest; on the contrary, the greatest producers have been mines possessing ores of very low grade, in large quantities, and so favorably situated that they could be worked very cheaply. When the production had fallen into the hands of a few companies, an agreement was entered into by a majority to keep the price up by restricting the production. In spite of its great power and strong financial backing this agreement could not be maintained, and the price has fallen from 20 to 50 per cent within the last twenty years. It might have fallen still lower had it not been for an increased demand for the metal consequent upon its extended use in electrical appliances. Although the consumption of this metal in the United States has increased fivefold since 1880, even some of the larger and more favorably situated mines find it advisable to close down from time to time and await a rise in the price; while many small mines, less favorably situated in regard to transportation facilities, have permanently given up the struggle for existence. In the long run, therefore, it is evident the supply of copper must be controlled by the demand, and no certain increase in the price can be looked for until the latter exceeds the former.

With silver there is less chance for the restriction of production, and the creation thereby of an artificial rise in the price of the metal, for the reason that the producing mines are much more numerous and their ownership less likely to fall into the hands of a few individuals or corporations. If, then, the production of this metal be not affected by legislative action or international agreement, it will be more subject to the law of supply and demand than copper. Among producers the law of the survival of the fittest will prevail, and the fitness will be determined by industrial conditions quite as far as by natural supply of ore. There will always be a certain proportion of silver-producing mines standing upon the border-land between working at a profit or at a loss. Such mines will close down with a fall in the price of silver below a certain limit, and start up again when its rise above this limit seems to have assumed a reasonable permanence, the limit being dependent on the industrial conditions that prevail in different localities.

Under existing conditions, as already shown, it is probable that the silver production of the United States will show a considerable decrease in the next few years. Probably that of Mexico and South America will be similarly affected, but possibly to a less degree, as their ores are relatively richer, and their mining industry is established on different industrial conditions and somewhat influenced by varying political complications. The product of Australia, as already shown, has already experienced a decrease likely to be permanent under present conditions.

It is therefore reasonable to look for a very decided decrease in the world's production of silver, probably to \$150,000,000, or even less if the expected increase in the gold product does not occur. In any event it is only a question of time, and probably not of very long time, when the relative production of the two metals will be about equal, as it was at the commencement of the decade. When in the downward course of the one metal and the upward course of the other the line has been crossed, and the relation between the production of the two metals shall be the reverse of that which now prevails, a decided rise in the price of silver may be looked for, which will render the mines upon the border-land again productive, and restore prosperity to the silver industry as a whole.

THE 46th anniversary of the discovery of gold in California was celebrated Wednesday, Jan. 24th, in San Francisco, Chicago, New York and other places, by various associations of California pioneers. It has not been so very long since the first nugget was picked up, but quite a good deal of history has been made since.

If new processes of working low grade ores, yielding \$5, \$8 and \$10 per ton can be applied, as the MINING AND SCIENTIFIC PRESS says, then there are hundreds of mines in Shasta county that can be made billion producers but which are now regarded with almost indifference.—Shasta Courier.

What has been done can be done.

*Abstract of a review of the Precious Metal Industry in the United States, contained in the "Mineral Resources of the United States," just published.

†It has not occurred during recent months with silver even at lower figures. It is true that a number of Colorado and Montana smelters were idle for awhile, but most have started up again.

Mines and Mining in Nevada County.

From Our Regular Correspondent.

The mining industry of this county is steadily progressing. New mines are being developed that bid fair to excel some of our famous gold producers when properly opened up. Since my last correspondence some rich rock has been extracted from the Electric and South Idaho mines, which has given renewed hope and energy to the stockholders. There are other facts which prompt us to believe that we are entering upon an era of unprecedented prosperity. The Omaha and Lone Jack consolidated mines last week paid a dividend of 15 cents a share, and Superintendent Mainhart informs your correspondent that the prospects of the mine were never brighter. At the Hudson Bay, one of our most promising prospects, the miners have passed through the hard rock, the present ground being more stratified and giving indications of a close approach to the rich ore shoot which is known to exist in this locality. At this mine they have only 20 feet to sink before they encounter the vein, which the owners hope will make them as rich and famous as their predecessors. Many hundreds of thousands of dollars have been extracted from the section in which this mine is located, and there is every reason to believe that the Hudson Bay is destined to become one of the future gold producers.

A new quartz mill has been erected on the Spanish mine at Nevada City. It is equipped with all the appurtenances of a first-class mill. It is stated that the mill will be kept busy night and day, crushing the ore extracted from the mine. The prospects of this mine are exceedingly favorable, the ledge producing ore in large quantity and of good quality.

Preparations are being made at the Granite Hill mine for a Midwinter Fair exhibit. We owners are highly elated over the possibility of their making such an exhibit. They realize the importance of such an undertaking and the great good that will accrue therefrom, hence their prompt and praiseworthy action. Considerable development work is being done at the mine, and the ledge promises to be a large and valuable one.

A few days ago some splendid looking quartz was brought to town from the South Idaho mine. The quartz contained gold all through and was extracted from the 140-foot level east. This mine is owned chiefly by residents of this city, who are working it with commendable energy. The shaft is 155 feet deep, and is being sunk on the vein; and we hope the efforts of the company, which is composed of business men and miners, will be crowned with success.

Last week I referred to the purchase of a new mill by the Electric Mining Company. This week it is my pleasing duty to state that a rich ledge has been discovered in the shaft at a depth of 350 feet. The ore is pronounced as being equal to any ever discovered on Osborne Hill, and promises surprising developments in the future. The ledge is from 16 inches to 2 feet in width. This is good news for the Electric Company, and I heartily congratulate them on their newly-found wealth.

At 8 o'clock on Wednesday night of last week the pump at the Idaho-Maryland mine made its first stroke since the fire. The pump was idle just eight days, and the management of the company are to be commended for the energy and enterprise displayed in bringing about this satisfactory result. The pump is working regularly day and night, and in a very short time the mine will be relieved of its water. A large number of men are employed repairing the shaft and constructing new buildings, and when this is accomplished operations will be resumed on an extensive scale.

Yesterday your correspondent, in company with Altonso Tregidgo, M. E., paid a visit to the Omaha and Lone Jack Consolidated mines. We were met at the mine by the affable and courteous superintendent, Geo. Mainhart, Esq., M. E., who personally conducted us through the works, both on the surface and underground. Every point of interest was explained by Mr. Mainhart with a precision that indicated a mind well stored with information concerning the property of which he is the efficient manager. The present standing and prosperity of the mine is due to the energetic and enterprising efforts of Mr. Mainhart, who has superintended the mine since its rehabilitation some years ago. Although it has been an uphill fight, and numerous obstacles were encountered that would dishearten a less courageous character, this gentleman has persevered, and is to-day enjoying the reward of services faithfully performed.

The Omaha & Lone Jack Consolidated is one of our

most famous mines and possesses an enviable reputation. The mine is great in extent and wealth and increases in richness as depth is attained. The property is a consolidation of the Omaha and Lone Jack mines and has an extent on the vein of 2600 feet. The mine has two incline shafts, each having attained a depth of over 1500 feet. At the present time, development work is being done entirely in the Lone Jack property. These two mines were connected at the 1400 level. The Lone Jack shaft is being sunk below the 1500 level and contains a large vein of ore which is very productive. The ore is hoisted through the Lone Jack shaft to the 1400 level, from whence it is conveyed in cars to the Omaha shaft, where it is hoisted to the surface. This system is necessary because of the lack of motor power at the Lone Jack shaft; but this is very expensive, necessitating the employment of several sets of carmen, and Mr. Mainhart informed me that during the summer a new hoisting engine will be placed at the Lone Jack shaft and will be propelled by electricity. This will cut down the expenses of hoisting and greatly facilitate the development of the mine. As already stated, the prospects of the Omaha Con. were never brighter. Last week a dividend of 15 cents was declared and another one is almost ready for declaration. The ledge in the mine is large and full of gold-bearing ore. It seems that the ground in the Lone Jack shaft is undergoing a process of evolution, passing from granite into a diabase formation, such as the North Star, New York Hill, Hudson Bay and the Peabody mines contain. The management and all mining experts consider this as a favorable omen for the future prosperity of the mine. A large number of men are employed at \$3 per diem. The mill, which consists of 28 stamps, is kept busy day and night crushing ore from the mine.

Grass Valley, Jan. 23, 1894 SAMUEL BUTLER, JR.

Mining in Siam.

Following is an outline of the conditions under which prospecting licenses and mining leases are now granted in Siam:

1. Prospecting licenses are granted for a period of 12 months from the date of issue, and extend over the whole of the province for which they are taken out; the fee is 40 ticals (\$24), and the necessary passports accompany them.
2. Exclusive prospecting licenses may be taken out for a specific area (of which a sketch plan should be supplied) and the area is secured for prospecting purposes to the holder of the license.
- The other conditions are the same as for prospecting licenses, except that the fee is 80 ticals (\$48); the license gives ordinary rights over all the remainder of the province. Both the above are renewable.
3. Leases of mining areas are given to holders of prospecting licenses. The application should be accompanied by a sketch plan of the area required, and fairly representative samples.
4. The term is 25 years, renewable if desired.
5. The size of the areas are as follows:
 - (i) Thirty acres on a well-known lode within five miles of an existing mining area.
 - (ii) Eighty acres on a new lode within five miles of an existing mining area.
 - (iii) One hundred and fifty acres on a new lode in a new mining district.
 - (iv) One hundred and fifty acres, 240 acres and 450 acres respectively in the case of quarries, placer, iron and coal mines.
 - (v) Five acres for mill sites outside mining areas when necessary.
6. The number of areas taken up need only be limited by the pecuniary position of the grantee.
7. The stamp fee on the signing of the indenture of lease of each area is 50 ticals (\$30).
8. The royalties payable are:

Three per cent on the gross product on gold and precious stones.

Two and one-half per cent on the gross product on coal, lignite and iron.

Four per cent on the gross product on all other metals and minerals.

9. The yearly rent is at the rate of two ticals (\$1.20) per acre; royalties and rent are payable half-yearly.

10. Necessary passports accompany the indenture of lease.

11. The lessee's covenants include supplying the department with an accurate map of the area and work, and samples of geological and mineralogical specimens met with, erecting boundary marks, continuing active work, etc. In case any area does not pay, it may be, under certain conditions, surrendered at any time during the 25 years.

12. The lessee of a mining area is required to have an agent in Bangkok registered at the office of the department.

Proceeds of Nevada Mines.

The annual report of State Controller R. L. Horton shows that the total bullion product of the mines in Nevada for the twelve months beginning October 1, 1892, and ending September 30, 1893, was \$2,501,169. Storey county is credited with \$1,270,008; Elko, \$188,729; Esmeralda, \$19,320; Eureka, \$371,562; Humboldt, \$9334; Lander, \$206,345; Lincoln, \$162,950; Lyon, \$35,134; White Pine, \$7865. This statement represents the bullion yield of ores. Following is the product from tailings: Lincoln, \$5000; Lyon, \$66,691; Ormsby, \$133,713.

The product credited to Ormsby and Lyon should be added to that of Storey county, as the bulk of the tailings worked in Ormsby and Lyon county mills represent the residue from the reduction of Comstock ore, and this swells the total bullion yield of Storey county to \$1,470,000.

The *Enterprise* estimate of the total bullion product of Comstock for the year 1893, published in the issue of December 31st, included the twelve months from January 1st to December 31st. The statistics of the last quarter of 1893 not being obtainable until next month, the product of that quarter was estimated and the total yield for the year placed at \$800,000. The total product for the State for 1893 was estimated at \$3,000,000 in the same statistical article.

Sliokens.

JOHN F. REED has charge of the San Bernardino county mining exhibit at the Midwinter Fair.

THE January rains have started up mining in the placer and shallow diggings in Shasta county.

THE Omaha Mining Company has declared a dividend of 15 cents per share which is now payable.

THE Grass Valley Union is getting out a Midwinter Fair edition of 10,000 copies. It is expected to excel any similar edition ever issued in that part of the State.

THE "180" mine, in Bendigo, Victoria (Australia), recently referred to in this paper by Mr. T. A. Rickard as being the deepest mine in the world, being 2900 feet deep, has reached the 3000 level.

THE Copper King mines, above Clifton, N. M., were "jumped" by a party of prospectors when the new year began. They learned later that the owners of the property had filed papers to hold the mines without doing work, hence the energy of the jumpers was wasted.

THE Alta Sierra Gold Mining Company has filed articles of incorporation. Principal place of business, San Francisco. Capital stock, \$1,500,000, with Frank P. Paterson and W. W. Watson of San Francisco, T. H. Henderson of Oakland, Thos. C. Pedler of Golden Gate, and J. M. Whitworth of Berkeley as directors.

THE Dutch Mining and Milling Company has filed articles of incorporation. Principal place of business, San Francisco. Capital stock, \$1,500,000, with Albert Trittenbach of Sonora and Thomas M. Carroll, Emil Trittenbach, T. J. Sullivan, G. Trittenbach, John H. Sievers and W. H. Metson of San Francisco as directors.

THE Allison Ranch Ford Gold Mining Company has elected as a board of directors, Edward Commins, D. S. Collins, Henry Silvester, Martin Ford and Daniel Brown. The board has organized by electing Edward Commins, president; D. S. Collins, vice-president, and Edward Fitzsimmons, secretary. In all probability active operations will commence on the property before very long.

THE search for the lost Pegleg mine has not been abandoned, notwithstanding the lives that have been lost and the suffering endured in search for the location of this mysterious property. Another expedition is said to be quietly fitting out in Los Angeles, which, it is claimed, is in possession of newly discovered evidence as to the mine's whereabouts. Men of means are reportedly backing the venture, and the expedition is to have a very auxiliary to a successful search that money can command.

COMMENTING on a reference to the Utica mine, in a recent issue of this paper, the *Amador Ledger* says: "The Kennedy is also an example of what has been accomplished by development upon a property which was lying idle and thought to be worked out. When F. F. Thomas secured a bond on the property and began its development by sinking, it had been idle for many months, but for several years past and at present it has been making handsome returns to its owners." "Handsome" is a very moderate adjective to use for a property that paid \$480,000 clear profit in 1893.

THE Sierra Nevada Mining Company has elected the following officers: President, C. H. Fish; vice-president, C. Hirschfeld; Secretary, E. L. Parker; superintendent, Roger Prendergast; vice, A. J. McDonell; directors—Charles H. Fish, Charles Hirschfeld, A. K. P. Harmon, Thomas Cole and H. Zadig. Out of a total of 100,000 shares 88,774 were represented at the meeting. The new superintendent has charge of the work in the Union Consolidated mine from the 900 level, of which the joint Sierra Nevada drift is being advanced into the latter ground. It is rumored that there will be an increase in the number of miners employed in the Sierra Nevada next month.

A MINER and prospector, lately from Colorado, warmly criticises the system in vogue in Arizona of working mining locations. He says the prospector finds a fair showing of ore, but all around he finds monuments, without the slightest indication of work done on the property other than the piling up of the stone corners. It may be that the property has been abandoned for years, owner may be dead, but in order to find it out the prospector has to take a trip to the county seat and hire some one to look over the books for him. Some of the Arizona prospectors are holding on to 30 or 40 "mines," upon each of which they, unaided, pretend to do \$100 worth of work per year.

Hydraulic Mining.*

A REVIEW OF THE INDUSTRY BY DR. HENRY DEGROOT.

In Eight Parts—Part V.

Water-Distributing and Gravel-Washing Apparatus.

While the dam and the ditch with its appurtenances are being constructed the gravel-washing and the gold-saving implements and apparatus should be gotten on the ground and put in place, the point where they are to be located being immediately under and in close proximity to the lower end of the ditch. At its lower extremity the ditch empties itself into a section of flume, at the end of which is situated the bulkhead or pressure box, a large oblong receptacle, built of strong planks and so called because the head or pressure of the water is here measured.

Connected with or located immediately above this structure is the sand box, a square compartment sunk several feet below the floor of the flume, the design of this box being to catch any sand or fine gravel coming down the

being brought into a placid state in the upper before it enters the lower one. That the water supply and exhaust be kept in equilibrium as near as may be, a waste gate should be placed in the flume above.

The main supply pipe starting from the bulkhead should descend to the washing pit with as few deflections, rises or depressions as possible, as these not only tend to retard the passage of the water through the pipe but also promote the collection of air within it, rendering an explosion imminent. To obviate this at all times and to guard against it when filling the pipe, at which time it is much increased, air valves are to be placed at suitable intervals along it. All large water pipes should be equipped with a sufficient number of air valves, these escapes being provided with brass floats, as the wooden ones are apt to swell, and becoming wedged in the valves, the pressure of the air without is insufficient to press them down. When the bank down which the pipe has to be carried has much inclination it should be placed on a stout frame work, and, besides

ter to be transmitted through it, a pipe 22 inches in diameter being sufficient to pass anywhere from 1500 to 2000 miner's inches. When the quantity of water ranges from 3000 to 4000 inches a 30-inch pipe should be chosen, the friction caused by the passage of the water being less, comparatively, in large than in small pipes. The iron used in the construction of these pipes varies from No. 16 to No. 11 and lower, according to the pressure to which they are to be subjected. For a 22-inch pipe No. 16 iron is usually employed for pressure up to 150 feet; No. 14 from 150 to 200 feet, and No. 12 from 200 to 300 feet, the latter being about as great a head as the water is apt to be used under in hydraulic washing. For a 30-inch pipe No. 14 iron has been found to answer for pressure up to 150 feet, and No. 12 from 150 to 275 feet.

Before being placed in position these and all other iron pipes to be used in connection with hydraulic mining should be immersed in liquid asphalt, such as is now being manufactured for this and similar purposes. Coal tar

ditch, such material, when it reaches this point, falling into the sink, being the depressed portion of the box, and is there retained. Through a gate at the side of the box this stuff is discharged as often as its accumulation makes it necessary. If much sand is allowed to enter the sand pipe it tends to impair the efficiency of its action.

The pressure box, with a width of about six feet, varies in length from ten to thirty feet, a greater length being required when it has two feed pipes to supply, also where the sand box forms a part of it. For the sand box a wooden apron is placed in the bulkhead and so arranged that it catches the sand and drops it into a chamber below, which is supplied with a discharge gate. A gate is set at the upper end of the pressure box to prevent any floating stuff entering it. There should be water enough in this box to cover the supply pipe to a depth of several feet, that no air, or as little as possible, be carried into it, to which end this box is usually divided into two compartments, the water

being braced on both sides, should be heavily weighted with boulders as a security against any movement which, should it occur, might cause much inconvenience and possibly serious damage. This pipe for several joints at its upper end is much enlarged to ensure a more free admission of water. Below that point it is all the way of uniform size, or as far down as the junction of the branch pipes, if any there are. In early times the letting on and shutting off of water was effected with a wooden gate, raised and lowered by means of a lever. For this crude and clumsy contrivance there has now been substituted in all large works the heavy cast-iron gate operated by a screw, powerful and easily manipulated. Everywhere now, on the dams, ditches and reservoirs and in the washing pits, these improved structures are in use, differing but little, except in size, and in this according to the service required of them.

A powerful machine of this kind is employed for admitting and shutting off water at the entrance of the main feed pipe. In the performance of this task care should be taken to let on the water gradually, as too great a rush might carry in so much air as to cause a disaster, this being a precaution to be always observed under similar circumstances.

The size of the feed pipe depends on the quantity of wa-

ter which these pipes were formerly coated, is now giving place to the asphalt preparation, it having been found equally cheap and more efficacious.

Formerly the lower end of the feed pipe was connected with what was known as the distributor, a short cast-iron box firmly anchored in the washing pit, the duty of which was to receive the water brought in by the feed pipe and distribute it to the several smaller pipes that lead to the giants or monitors, the number of these pipes corresponding with that of the machines to be supplied with water. Being ponderous, costly and liable to burst, the distributor has come to be pretty generally discarded, the plan of connecting all distributing pipes directly with the main feeder, as now practiced, having superseded it.

The accompanying plate presents a general view of a portion of the gravel-washing and the gold-saving appliances located in and below the washing pit.

A Rare Gold Story by Pliny.

Pliny, that rare old gossip, tells among his other extraordinary stories, that of the Bactrian method of obtaining gold, says an unidentified exchange. The sandy desert of Bactria in the days of that historian was, so the old man says, literally swarming with ants "slightly bigger than

*This article was prepared by the late Dr. De Groot for the Eleventh Report of the State Mineralogist, just issued; but its publication with that of much other valuable matter was prevented by the necessity of revision and omission, so that the volume might be reduced to reasonable limits. It covers familiar ground, but is, on the whole, a complete and careful review of the industry and hydraulic-mining methods. The article has been furnished this paper by State Mineralogist J. J. Crawford.

foxes." These gigantic representatives of the genus homonoptera burrowed deeply into the sandy wastes, their tunnels and galleries often being hundreds of feet in extent. The earth removed from these burrows was always carried to the outside and thrown up in hills (remember Pliny says this) "of a bigness exceeding a palace." This debris—sand, earth, etc.—was soon found to be wonderfully rich in small nuggets of gold. The danger from the ants was greater, however, than that from the Indians in the early days of gold digging on the coast, and many stories are told of men who were literally devoured in a few moments by the fierce owners of some disturbed burrow. Some observing old hunter at last discovered that the giant ants slept during the hottest hours of the day. After that the seekers after the yellow metal only made their incursions at the proper time, and even then they only stayed long enough in the desert to fill their sacks with the golden sand, which they took home to sift at leisure. With all this precaution the ants often "swiftly pursued the fleetest horses, and it was only by using various stratagems that the invaders managed to escape alive."

On the Colorado Desert.

Abstract of article by John R. Weeks in Santa Maria Times.

All that this country needs to make it a great wealth producer is plenty of giant powder and beans properly applied and mixed with a little brains. Last winter when we came out here a one-half interest in a claim was offered us for sinking 50 feet on it. The owner begged us to take it. It did not prospect over \$20 a ton on the surface, and my partner refused to touch it. I offered the opportunity to several parties, among others to a couple of enterprising citizens of Santa Maria, who declined. Finally a Frenchman took it, and sunk 75 feet. At 50 feet he had a six-foot vein of ore milling \$30 a ton and some of it away up in the hundreds. At the present depth the ore has turned loose, but richer still. A one-half interest in the claim is worth over \$25,000 to-day, and there is double that amount in sight.

There are more such opportunities for men of small means and backbone enough to undertake them. Still, you don't get such a chance every day. Another claim—the Carlisle—was purchased undeveloped for \$1100. An expenditure of \$3500 more has put about \$8000 worth of ore on the dump and about \$30,000 within sight below.

I have never been in a camp where you could go out and bring in so many samples of rich ore from different ledges as in this old Rattler district. In most camps there are only one or two or at most three good claims. Here are a dozen within five miles that will all make properties worth six and seven figures with proper development, and plenty more to be found. One claim in which I was interested 16 years ago, and abandoned, was recently sold, and a one-half interest brought \$12,500. I met the lucky seller, and we had a laugh over it.

I have in my pocket specimens of float, stephanite (75 per cent silver) that a year ago was worth over \$20,000 a ton, but thanks to Grover it is not worth looking for now. There is plenty here for all who have the necessary capital and sand enough to tackle the desert.

In my last letter I told you of being caught in a heavy thunder-storm in the middle of July and camping all night in the mud in the middle of a dry lake. The climate is rapidly changing for a wetter one, for a month ago I was caught in the same locality in a snowstorm of two days' duration. Most people have altogether mistaken ideas of the desert, and it is a bugaboo to the majority of people. The few drawbacks can be easily overcome after you get used to the change of conditions. Water is scarce and poor, but, by boiling thoroughly and using citric acid freely, it overcomes that difficulty. Experiment has proved that water can be had in wells in many places. Fuel is scarce, but gasoline is cheap and not as expensive as coal and wood on the inside.

Timber is scarce too, but little is needed in ordinary mining operations, as no water is met with in any of the mines so far explored. There is no expense for pumping machinery. To sum it all up, our ores can be mined and milled at the same or less expense than those closer to the coast and "inside," which run from \$15 to \$25 per ton, while our ores run from \$25 a ton up into the hundreds, and the sulphuret concentrates away up into the thousands.

There is very little danger in getting lost and dying on the desert if one uses ordinary precautions and has a little horse sense. Most of the cases have either been intemperate men or those who were too bull-headed to take advice. More than 90 per cent of them are whisky or beer drinkers. There are many more, however, than are ever reported in the newspapers.

The notorious Breedlove case two years ago was evidently not from want of water, but poison from something they had all eaten. Men dying from thirst do not die as they did, nor should men in ordinary health perish in so

short a time after water is exhausted. It is the healthiest country on earth. No one has been known to die a natural death out here. Whatever disease a man may have—rheumatism, catarrh, throat or lung complaint especially—the climate is a specific, and for eight months in the year is as delightful as can be asked for, never any fog, and so warm that I never put on a coat for seven months this season.

Va. Dale Mill, Colorado Desert, Jan. 10, 1894.

The Idaho Placers.

A correspondent at Caldwell, Idaho, thus writes to the Butte *Inter-Mountain*: The Snake, Boise and Payette have each given homage to thousands the past season who would have otherwise gone in actual want. The former's banks were lined from early spring until late this fall with both old-timer and pilgrim—the former with his oft-repeated tales of oyster-can "cleanups" in Alder, Confederate, Boise Basin and Jordan creek, the latter with his many inquiries and eagerness to learn the real causes of Snake's "golden-floored" waters. As of old, a repetition of one condemning and others settling on a bar has been the result all season.

The number of colors in a pan of Snake pay dirt excites the best of 'em, but, contrary to the reports sent broadcast all summer concerning the rude methods and big cleanups, readers of your valuable paper, especially those contemplating casting their lot with old Snake, should be warned in time that \$1.50 per man with rocker would be a conservative average of the output all summer. With the possible exception of a half-dozen bars from Shoshone Falls to Huntington, Or., which have run as high as \$4 per day with rocker, nothing has been demonstrated in flour-gold mining this year to encourage any one to leave a situation, no matter how small his remuneration. The great excitement caused by the trial of a new machine, said to catch invisible gold, has subsided.

These machines all have some merit, but, strange as it may seem, the inventive mind runs in gold-saving machines, while with them all no thought is given to a mode of raising water on to high river bars cheaply. All these machines require water, and trials in places with an irrigating ditch for supply look well; but place the same apparatus on a high river bar, with no water except the millions of gallons flowing hourly by, and it is not so encouraging.

New-fangled gold savers are of secondary consideration, for there are dozens of home-made machines that will save 90 per cent of the gold, and the cost to build is a little lumber, nails and labor.

Let those who spend their spare moments racking their brains on flour gold turn their attention to contriving means of getting water on our bars, and we'll do the rest. Then watch Idaho make strides for first place as a gold-producer.

Road Legislation in the United States.

The investigation into road construction and management in the United States by the U. S. Agricultural Department, and under Gen. Roy Stone as special agent, is said to be making good progress. State geologists are beginning to supply information as to materials available for road construction, and 50 engineers of railway companies have sent in reports. This material is now being tabulated and a map is in preparation which is to show the location and cost of the best available road-making material throughout the country. A bulletin is soon to be issued outlining the new road laws of 14 States.

General Stone will say that road legislation is proceeding on ten distinct lines, ranging from more rigid operation of the old system to the direct building of State roads. Tennessee gives the county courts full power and direct control over roads and eliminates local politics and prevailing easy-going methods. The courts classify the roads, establish districts, appoint commissioners and assess road taxes. Vermont, New Hampshire, North Dakota and Oregon increase tax levies for roads. The latter State allows county courts to levy a special tax of 50 cents on the \$100 and \$2 per head for a county road fund. New Jersey absolutely abolishes the payment of road taxes in labor and the abolition is almost absolute in Wisconsin. In Oregon, Indiana and by special acts in Ohio, local assessment applies to construction for a three-mile limit on each side of the road. In Oregon the county may assume half the cost, and in Ohio a large share is assessed upon the county. In Pennsylvania and New Jersey much work has been done by townships and by township bonds. The issue of county bonds is provided for in New York, New Jersey, Indiana, Michigan and Washington; but in the two latter States a popular vote is required to authorize the issue.

State highway commissions have been created in Massachusetts, Vermont, Pennsylvania, Ohio, Michigan and sev-

eral other States. Massachusetts has the only permanent body of this character charged with important duties connected with actual road construction; the other commissions can only inquire into existing conditions and recommend methods for improvement. New York is experimenting with convict labor on roads near the Clinton prison, and Tennessee law makes available for this purpose all prisoners confined in county jails or workhouses.

New Jersey is probably the only State giving direct aid to road-building. The report says: "This aid is limited to one-third of the roads built by the counties and to the sum of \$75,000 per annum. The highway commission of Pennsylvania has reported a bill for State aid to the amount of \$1,000,000 per annum to be distributed among townships in proportion to the road tax paid by them. The townships, according to this bill, must set aside 25 per cent of their tax for making permanent highways. Co-operative road-building, as provided for in New Jersey, has been very successful. Abutting land-owners pay one-tenth of the cost, the State one-third, the county the remainder, by sale of bonds. Under this law, ten miles of road were built in 1892, 25 in 1893, and 64 are applied for by land-owners for 1894.

The data already gathered shows that new roads are constructing in many parts of the country and that increased knowledge and skill, improved machinery and methods and extended practical experience are rapidly lessening the cost of good roads. Civil Engineer Harrison of Asbury Park, N. J., is authority for the statement that, while three or four years ago the cost of road-building was \$10,000 per mile, it was last year \$3500 a mile. Prof. J. B. Hunnicutt, of the University of Georgia, in response to an inquiry from the bureau, states that the cost of good, hard roads recently built in Georgia, providing for a track of stone and one of earth, was \$1200 a mile. Supervisor Chapin of Canandaigua, N. Y., in a letter to General Stone, reports that ten miles of a single-track stone road, with an earth track each side, was built in that town for \$700 a mile. Active interest in the movement for better roads is shown by the railroads generally. Special or reduced rates are offered by many railroads, and a tabulated statement of the various concessions in shipment rates by a large number of companies has been prepared.

What Silver Demonetization Has Done.

Extract from Review of Eureka District and County, Nevada, in *Weekly Sentinel*.

The review of the mining operations of Eureka county in 1893, which we herewith publish, will serve to illustrate to the world the effect of the demonetization and low price of silver on Eureka district, which, since its discovery in 1864 and the commencement of its active development in 1870, has yielded in gold, silver and lead in the neighborhood of \$125,000,000, and in 1878 produced in gold and silver alone \$5,500,000 from 238 mines, big and little, then under active development. The average value per ton in gold and silver of all the ore that was mined in Eureka county during that year was \$45.40%. During the last year, 1893, there were only 30 producing mines and three prospects under development in the entire county. Among them the Diamond mine was the only one that cut any figure in active development or the employment of miners on days' pay.

During 1892 the average number of miners engaged in the county was 140 on days' pay and 200 leasing, tributizing and working on own account. Last year the average number was 83 on days' pay and 127 leasing, tributizing and working on own account. Out of a total average of 210 miners in the county Eureka district gave employment to 172 men, 68 of whom worked on days' pay and 104 on lease, tribute and own account. The figures show a decrease last year of 57 days' pay miners and of 73 men under lease, tribute and on own account, and a total falling off of 130 men, or 38½ per cent., of the previous year.

The yield of ore from all of the producing mines of the county during the year 1893 aggregated 14,606½ tons, with an approximate gross value of \$26 per ton, and 14,515 tons out of the entire yield of the county came from the mines of Eureka district. Following are the names of the producing mines and the number of tons yielded by each for the year 1893:

From the Bullwhacker, 297; Dead Broke, 11; Delaware, 117½; Diamond, 6,639½; Dunderberg, 401½; Ethel, 23; Eureka Consolidated, 3,171½; Hamburg, 942½; Idaho, 30; Jackson, 1,084½; Lord Byron, 28; Maria, 12; Needle, 3; Phenix, 163; Pioneer, 83; Richmond, 1,135; Silver Connor, 59; Silver Lick, 7; Silver West, 18½; Williamsburgh, 84; small lots by consignees, 205½; Cortez mines (limited), 36; Comet and Good Luck (Safford district), 5; Island Queen (Cortez district), 11; Lincoln (Diamond district), 11; Sada Lindsay (Union district), 28.

The 36 tons from the Cortez mines (limited) were valued at \$7,600, or \$211.11 per ton. This is the greatest mine in

Eureka county to-day, both in the extent of the mineral lands and richness of the ore. No active work has been done in it for over a year, because of the low price of silver. The Comet and Good Luck mine at Safford district is said to be a good property. The 5 tons of ore shipped from there were taken out by one man, who is in charge of the mine, and netted over \$1,000.

What the low price of silver is doing for Eureka county may be estimated from the following statistics for the years ending September 30, 1891, 1892 and 1893. For 1891 the yield of ore from Eureka county was given as 27,664 tons, with a total gross value of \$904,523.27, or \$32.70 per ton. The cost of extraction, transportation and reduction

The Diamond mine has come to the front and is steadily increasing its output and value. For the year ending Sept. 30, 1892, it yielded 8,996 $\frac{3}{4}$ tons, with a total value of \$188,100.33, or \$20.90 per ton. For the year ending Sept. 30, 1893, notwithstanding that the mine was idle during the half of July and all of August and September, and under active development only 9 $\frac{1}{2}$ months, the yield was 8,008 $\frac{1}{2}$ tons, with a total value of \$230,802.10, or an average of \$28.81.

The Eureka Con. mine, for the year ending Sept. 30, 1892, produced 6,226 $\frac{3}{4}$ tons, with a total value of \$119,288.63, or an average of \$19.16 per ton. For the year ending Sept. 30, 1893, the entire yield reached only 3,011 tons,

The Greatest Building at the Midwinter Fair.

The Midwinter Fair is progressing toward completion rapidly. The management has declared that the great opening shall take place on Saturday, January 27th (to day), and the Governor has declared a public holiday on that date.

We introduce on this page a view of the main entrance to the largest building on the grounds—that devoted to manufactures and liberal arts. It is of Moorish design, 450 feet long and 250 feet wide, its height being 55 feet, and it has an annex 75 feet in width, nearly the whole length of the structure. It has all the picturesque

MIDWINTER FAIR—THE GRAND ENTRANCE OF THE MANUFACTURES AND LIBERAL ARTS BUILDING.

amounted to \$781,807.39. The yield of 1892 was 24,533 tons, with a gross value of \$790,714.22, or \$32.23 per ton, and the costs \$550,471.36.

The yield of 1893, with the big drop in the silver and lead markets, was only 14,755 tons, with a gross value of \$390,044.20 and costs of \$372,893.88. The average value per ton of all of the ore mined in the county during the year ending Sept. 30, 1893, was only \$26.43, and if the yield at the Diamond mine with 8,008 $\frac{1}{2}$ tons at \$28.81 is excepted, the average value per ton of the balance of the ore mined in the county during the given years was only \$23.59. The reasons for the reduced average value may be found in the low prices of silver and lead, the comparatively small amount of new ground broken and the fact that the lessees and trippers confined their work to prospecting the old mines and scratching around old ore chambers in place of mining for new ore bodies in virgin ground,

with a total value of \$65,061.48, or \$21.61 per ton, being a decrease for the year of more than 50 per cent in the tonnage, but an improvement in the grade of the ore.

The Richmond mine, for the year ending Sept. 30, 1892, produced only 1,153 $\frac{1}{2}$ tons, with a total value of \$40,074.35, or \$26.48 per ton. The yield for the last year, ending Sept. 30, 1893, recorded a very serious falling off, inasmuch that it reached only 913 tons, with a total value of \$19,176.88, or \$21 per ton.

THE Austin *Reveille* says that the Pradier Bros. of Austin, Nev., have handed to Salt Lake City capitalists one-half of their antimony property located on Big creek, Lander county, for the sum of \$35,000. The finest antimony yet found has been taken from this property. Expert testimony proves this to be a true fissure ledge from 50 to 60 feet in width,

ness that is so readily obtainable in this style of architecture, and with the colonnade which surrounds it, and its towers, will introduce the various forms so popular in the mission buildings. Roof gardens will be found in the loggias of the towers. The roof will be covered with encaustic metal tiles, and a skylight, and the building will be lighted from the top as well as from the sides.

THE Watsonville beet-sugar factory finished the season's run last Friday afternoon with gratifying results to the company and all concerned. Seven thousand seven hundred and sixty-nine tons of sugar were manufactured.

THERE is every indication that the settlers on railroad grant lands in southern California will be defended in the contest for their property by the United States Government,

The Alkali Metal Sodium.

From Article in *Scientific American*.

At its melting point sodium is as liquid, mobile and lustrous as mercury. It instantly tarnishes in damp, but not in dry air. It becomes pasty at about 122° F. At the ice temperature it is still ductile, but below zero Fahrenheit becomes brittle and crystalline. Sodium stands high as a conductor of heat and electricity, being in these respects surpassed only by gold, silver and copper. Hence, in cases where mercury is applied as a mobile liquid conductor, the liquid alloy might be preferable—protected, of course, from damp air, say by inclosure in a space communicating with the air only through a tube containing calcium chloride.

An American chemist, Charles A. Seeley, now deceased, discovered a surprising property of these alkali metals. They dissolve, as metals apparently, in liquefied ammonia gas, and on evaporation are left in their original metallic forms. The solutions are transparent and of deep blue color.

As aforesaid, the discoverer of the alkali metals found that mercury containing a little of them would enfilm or wet (so to speak), iron, steel and platinum. About 1840 an English chemist, Robert Mallet, discovered also that melted metals having no natural affinity for iron dissolve it rapidly when containing a little sodium or potassium. An American chemist, Henry Wurtz, took up these subjects in 1857, and carried them much further. He made very numerous experiments and inventions in this field, and patented some of them. The cost of sodium then ranged in this country from \$8 to \$10 per pound, and his inventions, patented prematurely, about 1865 or 1867, were, therefore, of no economical value and have long been public property. Now that it is proved, however, by Castner's work, that if a market exists for sodium it can be produced at a cost of 18 cents per pound, and the liquid alloy doubtless for little more, these forgotten devices should be revived and improved upon by supplementary inventions. Some of these methods of H. Wurtz were as follows:

First—A method of rapidly making these metals into solid amalgams, in which forms they can be handled, and their great energies and affinities utilized, without danger or difficulty. Combination with mercury involves great and usually highly explosive evolution of heat, which Wurtz obviated by a very simple device. Instead of starting with pure mercury, he employed a pasty amalgam, containing about two per cent of the alkali metal—this being about half saturated—for solid, hard, fully saturated amalgam of sodium contains but four to five per cent. A series of iron pans is set in a row, with a small Bunsen burner which can be moved from one to the other. A lump of sodium, averaging a third to a half ounce, is placed on the amalgam in one of these pans, with a little paraffine wax as a flux. The burner is then applied beneath, until the sodium, without any explosion, suddenly melts down into a thin cake of hard amalgam floating on the poorer amalgam below, which is itself liquefied by the heat of the reaction. This cake is removed with tongs to a ledge on one side of the pan to cool, and the next pan operated upon. Unless the number of pans is too large, the burner need be used but once with each of them, as the heat retained is sufficient to produce immediate combination. One operator could in this way make a thousand pounds daily of saturated amalgam without an explosion. The cakes are all melted together under paraffine in iron kettles, and cast into ingots or other shapes desired. To use the liquid alloy in this way some modifications will be required in the manipulation, which experiment and invention will readily evolve.

Second—A very little of such amalgam added to mercury was found by H. Wurtz to intensify so greatly the adhesion of the mercury to gold and silver that when these occur in ores in such forms as to be untouched by ordinary mercury, this prepared mercury instantly amalgamates and absorbs them.

Third—When mercury becomes "floured" or "sick," as it is called, a little sodium amalgam wholly cures it, and coalesces the detached globules instantly. The water in the apparatus slowly dissolves out the sodium, but it will be a very simple matter of invention, now that sodium is applicable with great profit to such ores, to devise plans of feeding the amalgam automatically to the battery and pans in minute graduated quantities.

Fourth—In alloying metals much trouble is often experienced through obstacles in the nature of such metals. Many such difficulties altogether disappear when a little sodium is present.

Fifth—Wurtz invented also the now familiar addition of sodium to various kinds of solders, and to baths for coating iron and copper with zinc ("galvanizing," so called), lead, tin and divers alloys.

Sixth—He devised a plan for removing the sodium and mercury (if present), when desirable, from such metallic coatings, by washing them out, so to speak, in a secondary

bath of the same metal. When this secondary bath becomes charged with sodium, it is used as a primary bath. The primary baths need not contain any mercury, as, with proper precautions the sodium itself may be incorporated directly with other metals.

The best "pickles" and fluxes for these widely varying operations of coating, etc., will become subjects of invention. We should warn experimenters that nothing can be done with *aluminum* in this field. Mercury destroys it rapidly.

The Old Dominion Copper Co.

Superintendent N. S. Berray has furnished the *Globe, Ariz., Silver Bell* the figures showing what was accomplished by the Old Dominion Copper Co. during the year 1893. It was, on the whole, a very unfavorable year for the copper industry; but, despite the low price of copper and the general business depression prevailing, the O. D. Co. makes a very satisfactory showing, due to a good mine and management.

The figures are as follows: Ore smelted, 63,597,300 pounds; lime used for flux, 14,618,208 pounds; coke consumed, 11,040,775 pounds; copper produced, 7,866,475 pounds, which is the second largest yearly output ever made by the company, having been exceeded, in 1892, when 8,019,059 pounds of copper was produced. The output during the fore part of 1893 was light, and the prospect for the year was further reduced by a suspension of about a month in the summer. That these losses were almost entirely made up during the last four months of the year is an indication of what could be accomplished with the Globe mine were the company disposed to increase the output. The development work done during the year amounted to 5620 linear feet, and the mine was never in better shape than at present, and the ore bodies show no signs of exhaustion. Also the smelting plant, cable tramway and other works are in a condition for efficient service. An important improvement made at the smelter was the introduction of the auxiliary windbox, now in use on all the furnaces, the value of which has been fully proven.

The management of the Old Dominion Copper Co.'s works is in good hands. Supt. Berray, during his long connection with the company, has worked in almost every capacity about the mine and is familiar with every detail of mine work. He has a capable assistant in the person of Louis B. Walker, whose technical knowledge is of great value. John Murphy and Wm. Ryan, who have charge of the smelting, and Frank Beston, foreman, and his assistants in the mine, are all old, trusted employes who understand their business. The company is fortunate in the class of men on its pay-roll, many of whom have been with them for years, and whose faithful services contribute to the company's success.

The Kennedy District.

Correspondence Winnemucca, Nev., *Silver State*.

Kennedy district is situated in an elevated, well-watered cove on the eastern slope of Clinch mountains, about 60 miles south of Winnemucca, from which place it can be easily reached by an excellent natural road.

In the lower portion of the cove we find the quartz mill, well-equipped restaurant, lodging-houses, barn and store—all substantial buildings and the property of W. T. Jenkins, who has already spent thousands of dollars here, and is now making arrangements for the erection of a roasting and smelting plant suitable for the more refractory ores.

The ledges of this district have a general north and south trend, dipping to the west at an angle varying from 45 to 80 degrees, and generally have a gangue composed of friable, decomposed ore bearing quartz. A few feet from the surface, water is usually struck, while the character of the ore assumes a material change, from what is claimed to be free-milling ore to a rebellious combination of great value. The well-defined, vigorous independence of the Kennedy veins from country rock, and other prominent characteristics of permanency, speak louder and plainer than words that nature's bandiwork intended that the ore fissures of Kennedy should remain as such. As a matter of fact submitted for serious consideration, the six square miles constituting Kennedy district are underlaid by an immense quantity of free-milling, roasting and smelting ores, ready to disgorge these treasures by proper metallurgical treatment, while in every instance the ore seems to increase either in quality or quantity with the depth attained. The dumps of Kennedy have considerable ore, showing the ready skill of the intelligent sorter and the indomitable energy of the untiring miner.

THE Southern Pacific is putting electric search lights on its engines up north, and the two Hogg engines running into Ashland, Or., are to be equipped soon. These search lights are very powerful and long-distance peepers into darkness, being able to throw a light for miles.

Artesian Wells as a Source of Power.

Abridged from Article in *Chicago Street Railway Review*.

Work has been quietly going on in South Dakota for the past year, which seems to prove that the artesian wells of the James river valley are as valuable and reliable a kind of water power as could be wished, and from all indications will continue to be so for years to come. Already a number of electric-light and flour-mill plants have been installed, and are in daily operation.

The artesian well district of South Dakota is located in the valley of the James river, covering a tract about 40 miles wide and 200 miles long. The James river is about half way between the Missouri and the eastern boundary of the State. The water-bearing rock is found at from 900 to 1000 feet from the surface. The first and most vital question that comes up is as to whether the supply is reliable, and can be depended on to continue with its present pressure, as more wells are sunk and a greater volume of water is drawn from the underground source.

There are good reasons for thinking that the supply is practically inexhaustible. These reasons are based both on the theories advanced by the United States government geologists and on observed facts in connection with the sinking of wells. The government theory is founded on the fact that the same stratum in which the water is found outcrops in the beds of the upper Missouri and Yellowstone rivers, and at the base of the Rocky mountains. The water, sinking in this porous stratum of rock, follows it for hundreds of miles, until tapped by the South Dakota wells. It has long been believed that there is more water in the Missouri river above the Great Falls than there is 30 miles below. For 25 or 30 miles below the falls the river bed is composed of the same sand formation in which the South Dakota wells get their water. If this theory is correct, as it probably is, the supply of water in these wells may be looked upon as inexhaustible—at least as much so as the sources of our Rocky mountain streams. Another fact that would point strongly to the truth of this theory is that during the June rise in the upper Missouri river the pressure in the wells rises. No diminution in pressure has been noticed in any of the wells in the district, except by clogging up with mud, due to improper piping. The city well at Redfield has been down seven years. Its pressure has been constant, although numerous other wells have since been sunk at no great distances from it. This well furnishes a direct pressure system of water works, supplying all the domestic needs of the city, and so great confidence is placed upon the pressure and supply that the fire department requires no fire engines. The closed pressure of this well is 177 pounds and cost for maintenance is absolutely nothing.

About a mile and a half distant is another well, used for running an electric light plant and for irrigation. A description of this well will suffice to give a fair idea of all. It is 1000 feet deep, and six inches in diameter from top to bottom. When closed, the pressure is 165 pounds. When allowed to flow freely through the six-inch pipe, it yields 207 gallons per minute, and rises to a height of 16 feet in the air. When the water is escaping through a two-inch pipe the well pressure is 128 pounds, and with a 2¾-inch opening 95 pounds. From this it is estimated that with a four-foot Pelton wheel, 80-horse power would be developed with a two-inch opening, and 100-horse power with a 2¾-inch. With the plain undershot wheel at present in place, 50-horse power is developed, and it is calculated that about 15 more is available with it. The flow is absolutely steady. This well cost about \$3000.

At Chamberlain a 150-barrel flour mill and light plant, formerly run by steam, is now using "well-power." These two plants were started in September, 1893. At Huron a well is about to be sunk by the city, for electric lighting purposes. The first electric light plant in the State, run from a well, is at Mellette, a town of 400 inhabitants. It is safe to say that very few plants in the world are doing a paying business in so small a place. This plant is thriving, however, and has connected to four-ampere arcs and 150 sixteen-candle power incandescents. The well is only four and one-half inches in diameter from top to bottom, but it operates, besides the electric light plant, a flour mill, which grinds 150 barrels of flour a day and 50 bushels of feed per hour. This work would require an engine of 40-horse power. The well is 910 feet deep. Its pressure when closed is 178 pounds. The flow is 1600 gallons per minute.

The outlay for an 80-horse power well is about \$3000, the interest on which would be \$2.25 per horse power per annum. This, with the interest and depreciation on the water wheel, is the only expense for primary motive power, aside from labor. A \$300 or \$400 building gives the wheel and dynamo a good shelter. The repairs to the water wheel ought to be almost zero, and the skill of the men employed for attendance does not begin to be that required in a steam plant.

Scientific Progress.

Photography in Astronomy.

In course of a lecture at Golden Gate hall, San Francisco, Jan. 18th, on "Photographic Revelations in Astronomy," Prof. E. E. Barnard, of the Lick Observatory, said:

"Very few persons have seen any of the results of advanced astronomical photography, save the well-known pictures of the sun and the moon. Indeed, it is the privilege of the few, and only then when they have access to the great telescopes and observatories of the world. I may say that photography has practically revolutionized astronomy, for by its aid and that of the spectroscopic we are enabled to see component suns that increase the power of the telescope on Mount Hamilton at least 25,000 times.

"As an illustration of the results of this class of photography, let me tell you that in February, 1892, Dr. Anderson announced that a new star was visible in the constellation of Orion. Professor Pickering of Harvard had made photographs of this region, but up to 1891 there were no signs of the presence of the stranger. However, on December 10, 1891, he discovered this star that had been recorded two months previously by an amateur astronomer, who used the photographic camera in the course of his observations.

"In October of the past year a Mrs. Fleming, who is interested in the observations made by Harvard College, detected a new star that had been affixed on a plate made in Central America. At the present time the rays of the sun have obscured this new star to such an extent that it is not visible, but the Harvard scientific party is still waiting at Arequipa to record its character when it emerges from the field in which it is at present hedimmed.

"Photography is also being applied to the discovery of other heavenly objects, and in the strange zone between Mars and Jupiter there are myriads of stars and kindred heavenly strangers that are constantly furnishing points of absorbing interest to those who study the field with the assistance of the camera.

"Last year, out of 50 discoveries, only one was made by the naked eye, and of the total number 35 were revealed to a single observer."

At this juncture Professor Barnard, with an assistant, used a stereopticon to illustrate the wonders and beauties of his subject, first showing the Lick Observatory in its shroud of snow, and again by moonlight and in a dense fog. He facetiously referred to his

next picture as a lamp-shade, but upon a closer study it was manifest to the audience that it was a faithful likeness of the sun as it sank on the crest of the ocean. Its eccentric form and luminous reflection gave it an apt resemblance to a transparent shade.

Again, the screen showed the sun with its spots and surrounding mass of incandescent hydrogen. The grouping of bright spots and granulated surface were distinctly defined and to the unscientific gave a bewildering insight to the dazzling surface of the orb of day.

"The heat of the sun is an unknown factor to scientists," said Professor Barnard. "According to their estimates it varies from 3000 degrees to 180,000,000 degrees. One authority says that were the entire coal supply of Pennsylvania placed within its radius, it would be consumed in the fraction of a second, while the glacial masses would be almost instantly turned to steam."

A photograph of the total eclipse of 1893, taken in South America, plainly showed the luminous corona of the great body. Then came the transit of Venus across the sun's surface, in which the planet's insignificant size was graphically displayed.

A magnificent view of the moon's area induced Professor Barnard to say: "On the moon there is no life, no water, no atmosphere. All is a desert. In the south pole region of the moon it will be seen that the craters are inactive and that the volcanoes are silent masses of desolation." In referring to the mountains, valleys, plains and other configurations of the moon, Professor Barnard defined the distances as accurately as he would refer to the area between San Jose and Mt. Hamilton. "One mountain peak near the south pole of the moon is over 40,000 feet high—a greater altitude than that gained by any eminence of the earth," explained the professor.

Referring to the planet Mars and its canals Professor Barnard said that, in spite of repeated claims, there is no accepted theory as to whether intelligent life exists on Mars. As an illustration of the extreme sensitiveness of the camera a view was displayed which showed a projectile being discharged from the Zallnsky dynamite gun. Its flight when caught by the plate was at the rate of 600 feet a second.

A group of views of the Milky Way were shown and explained in a highly interesting manner. They were followed by a photograph of the double cluster of Perseus. It was remarked by Professor Barnard that the photographing of the comet of 1882, made at the Cape of Good Hope, was the real incentive for further research in astronomical

lines by means of the camera. As illustrating the particular beauty of the skies, a view of the Pleiades, with their nebulous rims, was thrown on the screen.

As a comparison of the relative power of the telescopic camera and the human eye, a group of views plainly manifested the stupendous difference, and this was accompanied by a graphic showing of the Lick telescope traversing a starry field in search of astronomical phenomena. Professor Barnard gracefully concluded his edifying address by saying, "The heavens declare the glory of God and the firmament showeth His handiwork."

Sensibility of the Eye.

It seems probable that some information as to the degree of perfection of the refractive system of the eye, and as to the ultra-microscopic structure of the cones of the retina, might be derived from a comparison of the smallest intensity of light that can be perceived under different conditions. Thus the light of a star which is just visible has been shown to be equal to that of a candle at a distance of 27,500 feet. Here the source of light may be taken to be a point of absolutely inappreciable dimensions.

On the other hand, Aubert (quoted by Prof. McKendrick) asserts that the minimum surface luminosity that can be seen is one of three-hundredth the brightness of the surface of the moon. The *Optician* estimates that the image of the moon upon the retina forms a circle of about 2025 times the area of one of the central-cone filaments. The total light distributed over this area will be, it is well known, equal to that of a candle at 12 feet. And one three-hundredth of it will be equal to the light of a candle at 208 feet. The light received by each cone may, therefore, be put at one two-thousand-and-twenty-fifth part of this. It is that of a candle at only 9360 feet. For a point source which is not of insensible dimensions this would seem to be the lowest appreciable intensity of light, or it is so if we assume the retinal cones to act independently of one another in perception.

Mechanical Progress.

An Improvement in Furnace Boilers.

At the fall meeting of the Alabama Industrial and Scientific Society held in Birmingham, November 24th, Mr. Murray, superintendent of the Linn Iron Works, described an improvement which he had been able to make in furnace boilers, whereby the use of a double-decked boiler with cylindrical mud-drum suspended beneath and a modification of the Spearman-Kennedy gas burner had resulted in notable economy.

Mr. Murray was obliged to dismantle a battery of boilers at the Alice furnaces, consisting of two 46-inch in diameter return-flue boilers 34 feet long. As these boilers did not give enough steam and the new boilers had to be put in the same space as occupied by the old ones, the problem had to be solved to secure the greatest heating surface in a limited space. The new boilers were built larger in diameter, and plain cylindrical heaters were added under each boiler. This new battery consists of two 54-inch return-flue boilers 34 feet long, each having two ten-inch flues. Under and connected with each boiler is a plain cylindrical heater 36 inches in diameter, 31 feet 2 inches long.

These heaters start eight feet from the front, giving room for the grate and the bridge-wall. The heaters pass through the back wall 2½ feet, and a 20-inch mud drum is suspended under the same on the outside of the brick work. The same setting, hangings and about the same brick work were used as in the old battery. The new double-deck boilers gave 1660 square feet of heating surface, as against 1040 square feet in the old style, a gain of 61 per cent. The supplementary heaters afford 59 per cent real gain. The increase of cost over the old system is only about 12 per cent.

Still better results were attained by introducing a separate jet of gas under the heaters, in addition to the one under the boilers. For this purpose Mr. Murray designed a new duplex gas burner. The upper burner is the ordinary Spearman-Kennedy burner. The lower burner is connected with the base of the upper one through a 9x9-inch cast iron pipe leading to a nozzle 24 inches by 3 inches. Air for combustion is admitted on either side of the battery through the hot walls, and envelops the gas jet at its orifice from all sides. The results with this burner were very flattering, and the same is now used by several of the furnace plants in that district.

Fire-Resisting Glass.

An interesting test of fire-resisting materials and construction was recently carried out in Berlin, under the auspices of the fire brigade and the insurance companies of the city, says the *Chicago Journal of Commerce*. The idea of the tests was mooted as far back as 1889; but there was considerable difficulty in arranging for a series of fires, which were intended to be as natural as possible and yet should not be dangerous. Finally, the municipality gave the experimenters the use of an old warehouse for their purpose; and this building, having been fitted up to represent various types of fire-resisting structures, was duly set on fire. Care was taken to subject the exhibits to the temperatures, irregularities of heating, sudden shocks by falling weights or jets of water, etc., which generally occur at conflagrations, and it was found possible to take fairly exact observations.

Among the most satisfactory results obtained were with the fire-resisting glass made by Messrs. Siemens of Dresden. The assessors declare it to be most suitable for any skylight or window necessary in a division between separate risks, as it will resist a temperature of 1300° C. for half an hour or more, bearing all manner of shocks and strains without suffering appreciable damage. Care is required in fixing this glass, how-

ever, as the iron frames generally used for the purpose buckle under heat and show, between the glass and iron, openings through which flame can pass. Some of the so-called fireproof floors made of iron girders and concrete came to speedy grief in these tests, while iron and brick floors stood very well. As regards fireproof doors, nothing stood better than double oak covered with thin sheet iron, between which and the wood there should be a layer of asbestos cloth.

Foundations in Quicksands.

At the International Congress of Engineering held in Chicago, Mr. F. Neukirch, of Bremen, read a paper on making foundations in quicksand. The sand on which the foundation is to rest is converted into solid concrete by blowing into it by air pressure powdered dry hydraulic cement. For this purpose a 1½-inch pipe is used, which is drawn to a point at its lower end and has three or more three-eighth-inch holes. This pipe is joined at its upper end by a rubber tube to an injector, which is connected to a source of compressed air, and is fed with dry cement.

The sinking of the pipe to the depth required is facilitated by blowing air through it during its descent and setting it in motion. Depth up to 19 feet can thus be quickly reached. This done, the cement is fed in and carried into the sand by the air, which, being forced up through the former, insures a thorough mixture of it and the cement. The tube is then slowly withdrawn, the supply of cement being continued until it reaches the surface. The concrete formed in this way takes several weeks to harden and requires some months to attain its full strength.

The whole area to be treated is divided into a number of small areas of about one square foot each. The tube being sunk successfully and operated on each of the squares, it is found that the mixture of the sand and cement produced occupies less space than the sand alone did before the operation. It has been used successfully in cofferdam work, also in sewer work, where it had to be laid in quicksand, it having proved highly successful in each case.

Another Smoke Consuming Device.

An ingenious German has invented a process which will in all probability win for him the gratitude of a long-suffering generation, says the *Ohio Valley Manufacturer*. He has devised a method the object of which is to remove the element of smoke from the combustion of coal; and so satisfactory have the tests been that the patentees have entered into contracts with some of the largest concerns in the country, including several of the principal lines of steamers. The coal to be used under this patented system is first reduced to powder by special machinery. This inflammable dust is projected into the current of air, automatically regulated, and as soon as it is inside it gives forth an intense blaze. Oxygen being introduced by an absolutely new contrivance, the dust does not fall to the bottom, but floats in space and is consumed to the last particle. There is never any smoke perceptible, nor any residue of ashes to be removed. The fire can be started or arrested in a moment, the pressure can be maintained at the uniform scale which may be required, so that practically there need be no waste of fuel, while the wear and tear of furnaces and boilers is greatly reduced. The invention is for manufacturing, smelting works, steamers and the like; it is not intended for private dwellings.

Aluminum for Engraving.

That aluminum can be successfully used for engraving in place of stone or steel plates has been successfully shown, says the *New York Sun*. The only stone used for lithographing is found at Sohlenhofen, Bavaria, and it grows more costly as the

supply decreases. A stone 30x40 inches, weighing 500 pounds, costs \$100. It is very fragile, and, being rigid, can only be used on flat surfaces. Under a recently patented process it has been shown that aluminum plates, weighing from 2 to 10 pounds and costing from \$5 to \$10, do the work quite as well. Besides, the metal is not fragile, and, being flexible, can be molded into forms for cylinder presses. As a substitute for steel in plates, the special advantage is that, while 80 to 100 impressions can be taken from a steel plate, an aluminum plate will furnish 8000 impressions. A company has been organized to manufacture the plates, and it is probable that their use will soon be widely extended.

Useful Information.

Sterilization of Milk for Children.

At the request of the Secretary of Agriculture, the Chief of the Bureau of Animal Industry has furnished the following simple directions for the sterilization of milk:

The sterilization of milk for children, now quite extensively practiced in order to destroy the injurious germs which it may contain, can be satisfactorily accomplished with very simple apparatus. The vessel containing the milk, which may be the bottle from which it is to be used or any other suitable vessel, is placed inside of a larger vessel of metal, which contains the water. If a bottle, it is plugged with absorbent cotton, if this is at hand, or in its absence other clean cotton will answer. A small fruit jar, loosely covered may be used instead of a bottle. The requirements are simply that the interior vessel shall be raised about half an inch above the bottom of the other, and that the water shall reach nearly or quite as high as the milk. The apparatus is then heated on a range or stove until the water reaches a temperature of 155 degrees Fahrenheit, when it is removed from the heat and kept tightly covered for half an hour. The milk bottles are then taken out and kept in a cool place. The milk may

be used any time within 24 hours. A temperature of 150 degrees maintained for half an hour is sufficient to destroy any germs likely to be present in the milk, and it is found in practice that raising the temperature to 155 degrees and then allowing it to stand in the heated water for half an hour insures the proper temperature for the required time. The temperature should not be raised above 155 degrees, otherwise the taste and quality of the milk will be impaired.

The simplest plan is to take a tin pail and invert a perforated tin pie plate in the bottom, or have made for it a removable false bottom perforated with holes and having legs half an inch high, to allow circulation of the water. The milk bottle is set on this false bottom, and sufficient water is put into the pail to reach the level of the surface of the milk in the bottle. A hole may be punched in the cover of the pail, a cork inserted, and a chemical thermometer put through the cork, so that the bulb dips into the water. The temperature can thus be watched without removing the cover. If preferred, an ordinary dairy thermometer may be used, and the temperature tested from time to time by removing the lid.

This is very easily arranged, and is just as satisfactory as the patented apparatus sold for the same purpose. The accompanying illustrations show the form of apparatus described.

Brickwork in the Tropics.

Bricks, when stones cannot be obtained, must of necessity be used for certain descriptions of work in the tropics, says the *Architect*. Great caution should be exercised in their selection, as it is found that all bricks made near the seaboard with brackish water are exceedingly susceptible to the weather, and molder rapidly away when exposed. It is, therefore, advisable to make them at some distance from the coast, with fresh water, and, above all, to have them well and thoroughly burned, which, in these climates, where fuel is generally most expensive, is most difficult to insure. Near the seacoast in Brazil it is found necessary to protect all brickwork with plaster, which certainly serves its purpose exceedingly well. In the interior of the country well-burned bricks may stand for a few years, but ultimately it will be necessary to plaster them, or to give them a thick coat of whitewash from time to time. Tar, over a coat of whitewash, has been used with considerable success for the protection of brick buildings and other works of this material, and in localities where it would not be considered unsightly, it is certainly preferable in buildings on the side from which the prevailing winds and rains set in during the wet season, as it not only throws off the moisture on the outside quicker, but tends to keep the interior of the building freer from moisture than any other protection. Of two samples of brick taken from the same wall, built in 1790, in Recife, although not in any way protected by plaster or lime whitewash, one appears to be quite perfect, while the other is rapidly decaying, and shows the necessity of outward protection, as a general rule, owing to the all but impossibility of obtaining in large quantities thoroughly well-burnt bricks.

The Telephotos.

The telephotos is a new means of electrical signaling by night and day. It is the invention of Claudius V. Boughton, of Buffalo, N. Y. The theory of the telephotos was the production by electricity, upon a shaft of incandescent lamps of any candle power, of the symbols of the Morse alphabet and numerals, in dashes five feet in length, made with ten lighted lamps, and dots of three inches made with one lighted lamp, and with unlighted intervals of five feet between each, which would bring under the eye the complete symbol at once, and was intended for use at any points within vision between which the laying of telegraph wires was impossible or impracticable.

Amount of Paint Required for a Given Surface.

It is impossible to give a rule that will apply in all cases, as the amount varies with the kind and thickness of the paint, the kind of wood or other material to which it is applied, the age of the surface, etc., says the *Clay Journal*. The following is an approximate rule: Divide the number of square feet of surface by 200. The result will be the number of gallons of liquid paint required to give two coats; or divide by 18 and the result will be the number of pounds of pure ground white lead required to give three coats.

New Sounding Device.

An instrument has been invented for sounding the depths of the sea without using a lead line, says the *Chicago Journal of Commerce*. A sinker is dropped containing a cartridge, which explodes on touching the bottom; the report is registered in a microphone apparatus, and the depth recorded by the time at which the explosion occurred.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new improved
Concentrating Belt manufactured in San
Francisco. We keep always on hand
Belts suitable for the Triumph and Frue
machines, but can make any length or
width desired. The advantages of these belts over
any others will be readily seen by practical millmen.
First, the flanges or edges of our belt stand at an acute
angle inclining toward the center, and therefore readily
conform to the change of direction while passing over
the end rollers; thus the vexation and loss caused by the
frequent breaking of the flanges of the old style belt is
practically done away with. Again, our belts, at intervals
of two to four feet, have a very slight rifled surface for the
space of three inches, which tends to equalize the pulp
on the belt, and prevents it from banking on the sides and
forming channels through the center. These slight rifles
also save very fine sulphurets and the quicksilver that
would otherwise escape with the tailings from a belt,
the surface of which is entirely smooth. We can safely
say that it is a better concentrator belt than has ever
been manufactured. It will last much longer and
will handle more pulp. We also manufacture smooth belts with same flanges when desired.

ASSAY OFFICE, SAMPLING WORKS,
AND
CHEMICAL LABORATORY,

524 SACRAMENTO STREET, - - - SAN FRANCISCO, CAL.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist
who has devoted many years to assaying and working pre-
cious ores on the Pacific side of the American Continent.
He writes whereof he knows from personal practice, and in
such plain and comprehensive terms that neither the scientist
nor the practical miner can mistake his meaning.
The work, like Mr. Aaron's former publications ("Testing
and Working Silver Ores," "Leaching Gold and Silver
Ores") that have been "successfully popular" is written in a
condensed form, which renders his information more readily
available than that of more wordy and less conscientious
writers. The want of such a work has long been felt. It
will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Ma-
terials; The Assay Office; Preparation of the Ore; Weighing the
Charge; Mixing and Charging; Assay Litharge; Systems
of the Crucible Assay; Preliminary Assay; Dressing the
Crucible Assay; Examples of Dressing; The Melting in
Crucibles; Reacidification; Cupellation; Weighing the Bead;
Parting; Calculating the Assay; Assay of Ore Containing
Coarse Metal; Assay of Roasted Ore for Solubility; To
Assay a Cupel; Assay by Amalgamation; To Find the Value
of a Specimen; Tests for Ores; A Few Special Minerals;
Solubility of Metals; Substitutes and Expedients; Assay
Tables.

The volume embraces 130 12mo. pages, with illustrations,
well bound in cloth; 1889. Price, \$1, postpaid. Sold by
DEWEY PUBLISHING CO., Publishers, No. 220 Market
Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead,
Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and is
separate from Part I, and treats of Gold and Silver Bullion;
Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion;
Assaying Bullion; Humid Assay of Silver; Gay Lussac's
Method; Volhard's Method; Manipulation; Lead Ores; Cop-
per Ores; Mercury Ores; Zinc Ores; Nickel and
Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur;
Salt; Note.

One of the methods given for the Assay of Copper is new
original, and exact, as is also one of the processes for Zinc.
The book contains 161 pages with illustrations, and is
strongly bound in cloth. Much of the original text is re-
placed by new matter.
Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING
CO., Publishers No. 220 Market St., San Francisco.

TIAL.

Electricity.

Electrical Fire Risks.

The interior wiring of buildings is a far more fruitful source of fire than overhead wires, and this class of construction calls for correspondingly greater care than the former. It is only within the past three or four years that interior wiring has been made perfectly safe, and this result has been largely due to the efforts and restrictions of the fire underwriters. Many of the devices used in the early days of incandescent lighting, and which at that time were regarded as thoroughly safe, could not now pass the inspection of an insurance company in the country.

Most of all the fires due to the use of electric lighting have had their origin in some part of the wiring of the buildings, as it is almost impossible to start a fire from an incandescent lamp; and where arc lamps are in use for interior lighting, the globes and screens in general use render them very safe if ordinary care is exercised in keeping them properly trimmed. The chief danger here lurks in the hidden part of the wiring, where a fire may attain considerable headway before being discovered; but if electric wiring is installed in accordance with the best practice known at present, its fire risk would practically disappear. As almost every one familiar with the subject admits the possibility of making interior wiring perfectly safe, it follows that where fires occur from this source, the work must be defective in some respect.

Faults in interior wiring may be traced to defective insulation, bad materials or workmanship and insufficient capacity of the wires, all of which may be detected with competent inspection, and which are generally the result of too cheap work, says a writer in *Electricity*. The insulation of any house wiring can be fixed at almost any degree demanded, even without the use of materials other than those commonly employed, if the work is put in by competent persons. The use of tubing in which to run the wires is now general, and this tubing consists of a non-inflammable material covered with a metallic sheathing, with which a complete system of piping is run through the building in the same manner as the gas or water pipes, and is provided with suitable outlets for lamps, switches, etc. In addition to the insulation provided by the tubing, the wire which is drawn through it is itself covered with a good quality of insulation, and only wires of one polarity need be run in a single tube. With those precautions, and the lines between the various outlets of ample capacity to carry their maximum possible current without excessive heating, no possible danger can arise on this part of the system.

The next point is the connections at the different outlets at which junction boxes of incombustible material should be provided. These contain the switches and fuse blocks, in which sparking and melting of fuse wires will inevitably occur at times, thus strongly arguing the use of only the most approved appliances of this kind. The use of wood or any inflammable material in these appliances should not be tolerated, although the old-time wooden bases are by no means obsolete. The apparatus used now, enclosed in slate or porcelain, meets every requirement of safety, but even this may be troublesome unless it is set up with care and is properly used. The chance of poor connections, and the introduction of light resistances at these points, is always present when this work is handled by any but the most experienced and careful workmen. If these fuse blocks are not properly used in regard to the size of the fuse wire required for the current, their use becomes a mere farce. It is certain that a great many cases could be found to-day where, after the proper size fuse wire has been melted, it has been replaced by copper wire of perhaps several

times the capacity of the wire it was supposed to protect from overload.

The same difference in quality and make may be found in the electric-light fixtures as in the other supplies, but their quality has been steadily improving, and, if properly installed, are very safe.

Four Different Lights from Molecular Vibration.

Mr. Nikola Tesla has demonstrated that the phenomenon of light is producible in four different ways by the action of high frequency electricity upon suitable media, says the *Scientific American*. One of these methods is the incandescence of a solid, consisting of a small carbon button mounted upon a platinum wire in an exhausted bulb. When Mr. Tesla connected his body with one of the terminals of a high-tension transformer, and took an arrangement of this kind in his hand, the button became luminous. Next he took a highly exhausted bulb, containing a strongly phosphorescent body, above which was mounted a small plate of aluminum on a platinum wire leading to the outside, and the currents flowing through his body excited intense phosphorescence in the bulb. Thirdly, he took in his hand a simple exhausted tube, and in the same manner the gas inside the tube was rendered highly incandescent or phosphorescent. Finally, he took in his hand a metallic wire, which appeared covered with a luminous film through the intensity of the electrical vibration. Mr. Tesla is now engaged upon the problem of producing these effects with less expenditure of energy than was employed in the operation at first arranged by him. Either method of converting molecular bombardment into light without heat, provided that it could be done economically, would be a considerable step forward in the direction where "the light of the future" is supposed to await its fortunate discoverer.

Continuous Electric Furnace.

In a recent issue of the *Comptes Rendus* of the Paris Academie des Sciences, M. Moissan describes a continuous electric furnace in which materials may be melted out of contact with the carbon vapor of the arc. The body of the furnace is constructed out of bricks of lime, surrounding a central cavity. The sides of this cavity are lined with alternate plates of carbon and magnesia, the latter being next the lime, as, if the carbon plates were in contact with the lime, combination would occur at the high temperatures reached, liquid calcium carbonate being formed. The magnesia plates are irreducible by carbon, and hence can only waste away by direct volatilization. The cavity is closed with simple plates, above which is placed a block of lime. The arc carbons pass through opposite walls of the furnace, and the arc is struck between them in the center of the cavity. Below the arc, and above the bottom, a tube of pure carbon one or two centimetres in diameter passes through the furnace from side to side, and is inclined at an angle of 30 degrees to the horizontal. The ores to be fused are placed in this tube and the arc struck. The metal as reduced flows down to the lower end of the tube, where it can be collected. Using a current of 600 amperes at 60 volts, M. Moissan has produced an ingot of chromium of two kilogrammes weight. The fused metal was cast in molds of sesquioxide of chromium, to which it gave up any carbon it originally contained. The heated part of the carbon tube is transformed into graphite.

Refined crystallized sugar, whether made from the beet or the sugar cane, is almost pure saccharose, and is the same substance in both cases. Few articles of food are so generally free from adulteration as granulated—not powdered or coffee-crushed—sugar.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

DRIFTS STARTED.—*Record*: At the Wildman mine drifts have been started at the 1300 level to tap the ledge. The station is cut out at the 1200, and operations will begin on that level next week. Superintendent Tregloan hopes to be getting out rock so that the mill can be started within the next four or five weeks. This will be good news to the force of men who were laid off three months since, when sinking from the 1100 level was begun.

STRAIGHTENING A SHAFT.—*Ledger*: A very hard piece of engineering is in progress at the Kennedy mine. This shaft is vertical 400 feet from the collar and from that point takes an angle of 56 degrees. This "corner" in the shaft has been a great source of expense on account of the wear and tear to ropes, track and skips and a decision was reached some weeks ago to reduce the angle by making a new shaft from 50 feet above the corner to about 50 feet below, the new shaft to be at an angle of 75 degrees thus making two easier angles for the skips to travel. The new shaft is about 100 feet in length and the point where it is farthest from the old shaft is about 18 feet. Thus it will be seen that a body of earth at least 18 x 18 feet, and wedged shaped 50 feet each way up and down the shaft had to be removed and the space occupied by it properly timbered. This work is not entirely complete, but on account of water and the fact that the north shaft is taxed to its utmost capacity, work was suspended on this improvement Monday and resumed later in the week. The preparatory work of laying out the plans of this improvement in the shaft was done by Master Mechanic Garbarini, while the execution of the work has been in charge of Foreman Trascott.

Mr. Wise of the Farrell has sent some fine samples of rock from his mine to San Francisco. They just made a cleanup in the mill, and will shut it down for a few days while Mr. Wise is absent upon a business trip in San Francisco.

Calaveras.

THE BLAIR.—*Echo*: The shaft on the Blair mine, at Smith's Flat, has reached a depth of over 210 feet, and very rich ore has been discovered. Cross drifts have been run east and west from the main shaft. Competent judges who have examined it pronounce it a valuable piece of mining property. The lead is represented as being nearly six feet wide and containing nearly 40 per cent of sulphurets of a high grade. The owners of this mine have spent a good deal of money in their endeavors to develop it.

Inyo.

REVIVAL LOOKED FOR.—*Inyo Independent*: There is every indication of a revival of mining interests in Inyo county. There are more men prospecting and new finds will surely be made. The Sorba mine is steadily producing good ore, and the more work is extended the more promising the mine becomes. The owners have already taken out enough ore to pay for the mine.

Mono.

STUCK IT AT LAST.—*Home Index*: Tbos. R. Rule has at last "struck it" in his claim at Mono Diggings, at the depth of about 70 feet. He went through a thick stratum of pipe-clay, which showed a little gold now and then. Under this he found genuine boulder clay. If he has really struck a channel that will pay, there will be hundreds of men at work in the old diggings next spring. Something like two millions in placer gold were taken out there in a short time, and its source has never been found.

Nevada.

THE GRANITE HILL.—*Telegraph*: Just now they "are getting in their work" at the Granite Hill mine. The ledge is getting to be a big one, and as we go to press the people who have charge of the mineral exhibit at the Midwinter Fair are rustling around to see the managers and owners of the mine to make an exhibit.

FINE ORE.—*Union*, Jan. 19: Some fine-looking ore, literally filled with gold, from the South Idaho mine, was being shown around town by Joseph O'Keefe, one of the principal owners. The company is working on the ledge which is two feet in size.

A NICE POCKET.—*Herald*: Another fine quartz specimen was found in the West Harmony Saturday, and Superintendent McCall will send it to the fair. It is a quartz boulder, found in the gravel. Upon breaking it open a pocket of beautiful gold was disclosed, light and flaky and as large as a hen's egg. Such boulders are being found right along in the West Harmony, and they are all put through the mill whether they look well or not.

NEW MILL STARTED UP.—*Transcript*, Jan. 18: The new quartz mill at the Spanish mine was started up yesterday. Everything works smoothly and satisfactorily and the stamps will be kept hammering away night and day on the fine quartz that is being taken from the mine. The mill is equipped with all the latest appliances, is conveniently arranged and most substantially built. Captain Nibell superintended the construction of the new mill.

AGAIN IN MOTION.—*Union*, Jan. 18: Last night about 8 o'clock the Idaho-Maryland pumping engine, which went through the recent fire, was set in motion and worked very satisfactorily, and will be kept running regularly until the mine is again clear of water. The mine is filled up to within 50 feet of the 1500-foot level, but it will be clear and dry in about two or three weeks if all goes well. The

insurance on the burned buildings and machinery of the Idaho-Maryland mine has been satisfactorily settled. The replacing of the buildings and machinery will probably be done by contract. Temporary sheds have been built for the use of the carpenters, engineers, blacksmiths and others at work at the mine, and everything looks favorable for the early resumption of mining in the depths.

Placer.

CRUSHING ROCK.—*Anburn Republican*: The new mill at the Three Stars mine is now crushing rock, and thus one of the most important mining enterprises in this part of the State has been entered upon. This mill is one of the finest in the State, and the property on which it is situated gives great promise of a future yield of the yellow metal. Success at the Three Stars means prosperity for the mining interests of the Ophir district.

THE HATHAWAY SALE.—*Republican*: Another big sale of mining property in the Ophir district, near Auburn, has just taken place, which means much for the future development and prosperity of that whole section. The sale just consummated is that of the Hathaway mine and Butts extension, the purchaser being R. R. Colgate of New York, and the consideration the sum of \$70,000. After making thorough tests, Mr. Colgate convinced himself of the worth of the property, and will go right ahead in his preparations to work the mine after the most approved modern methods. With two such mines as the Three Stars and the Hathaway in active operation, the Ophir district may expect an era of renewed prosperity.

Plumas.

BUILDING A DAM.—*National Bulletin*: J. H. Higinis has been building a restraining dam at Michigan Hill, to so enable him to operate his mine as to cause no fears that debris from it will reach the main stream. The structure is 297 feet long and will serve to impound a large amount of debris. As a matter of fact, the operation of this mine never has done any injury to the lower country, and the legal proceedings against it and the owner were persecution.

Riverside.

COAL AGAIN FOUND.—It seems as if there must be a considerable body of good coal in the Santa Ana ranges of mountains, south of town, says the *South Riverside Bee*. There are abundant indications of coal, and prospectors have at different times followed up small veins until their money or their patience gave out. The best result ever obtained was in Tin Mine canyon, where the Gilbert Brothers expended all their means. They developed an 18-inch vein of excellent coal. Their shaft filled with water and they had to abandon it. Several prospects are now being developed. Outside capital has been put into development of a claim owned by Judge Riche. The 50-foot shaft that had been put down has filled with water and a tunnel is now being driven. Several thin veins or stringers of coal have been out, and hopes are entertained that a good body will be uncovered.

San Bernardino.

BIG NUZZER.—J. D. Beam, Buynon Marsh and W. W. Wright, the three prospectors who left here, says the *Madera Mercury*, to prospect for a quartz mine in the newly discovered gold fields in western San Bernardino county, have returned. They brought with them a flat nugget which weighs 19 ounces and will probably assay about \$17 to the ounce. The under side of the nugget is smooth where it laid in the sand and the upper surface is irregular. The gold had been melted by volcanic action and was irregularly formed. It was found in a small wash in Goler canyon, about three feet below the surface of the ground. As all the claims in that country had been located, the prospectors did not prosecute their search very closely. Mr. Wright stated that the prospect for quartz mines is very poor. The ore is of a low grade and would not pay if it had been shipped to a mill. Water and wood are scarce, the prospectors having to carry a supply of both articles. They were forced to come back, as horse feed gave out. They will probably make another prospect soon.

TWO NEW MILLS.—*Vanderbilt Shaft*: The commencement of work by the two stamp mills now being erected will be the beginning of a new era in our camp. The number of men employed in the mills and mines connected therewith will be sufficient to make the payroll amount to \$10,000 per month, with only ten stamps in each mill. Besides these men there will be many other men who either have claims here or will lease parts of claims, and who will commence chloriding, as both mines will probably do custom work.

San Diego.

A NEW MILL.—The Escondido (San Diego county) Gold Mining Company has contracted for a 20 stamp mill, which is expected to be in operation at the mine by the 15th of February. The mine is proving very satisfactory, according to reports of those interested, and they hope to have some of the most improved machinery in operation there shortly. The ledge has widened to over five feet in thickness, and there seems to be a great deal of ore in sight.

Siskiyou.

NEW DITCH BUILT.—*Yreka Journal*, Jan. 17: Frank H. Hall, the enterprising operator in mines, has just completed a new ditch at Salmon river, and will start up work this week in operating the old Finley Tribe mine, recently purchased. The claim will be mined by the hydraulic process, with a good supply of water to continue until late in the summer, if not all year round.

The quartz mines at Oro Fino are turning out exceedingly well of late, and considerable

gold will be realized this season in that district. Rich strikes have been found in the Digglees claim, also in the old Banner claim and other ledges. The hydraulic claims are lying idle since New Year's in consequence of the cold weather freezing the water at the head of the ditches on in the high mountain altitude.

Some fine specimens of coal were brought into Yreka last Friday from the Siskiyou coal mine, at Willow Creek, for the Midwinter Fair. The owners are doing considerable work in opening this mine at present, and expect to realize a great amount of first-class coal during the coming spring and summer.

The warm rain of the past three days has filled all the streams and ditches to fullest capacity, and the hydraulic miners debarred last week from the effects of frosty weather can now start operations again on the most extensive scale, with water enough to use all the giants, and also ground sluice in uncovering the pay gravel at bedrock.

THE STORM A BENEFIT.—*Yreka Journal*, Jan. 24: The heavy rainstorm of a week ago, and the snowstorm of last Friday night, will be of great benefit to the mining interests, the rain having filled all the small streams and gulches, while the deep snow on the mountains will prove a valuable fountain in keeping up a good supply as it melts gradually every day until midsummer, if not longer.

We anticipate considerable work in the dry diggings and high gulch claims during the remainder of the winter and coming spring, as there is a great quantity of snow on the mountain summits to afford plenty of water for ground sluicing, especially when warm rains occur to melt the snow more rapidly.

The Greenhorn blus gravel mine is now supplied with an abundance of water, and a large force has been employed with good success in securing a much larger yield of gold each day. The water supply will last until late next fall, as there has been more rain up to date than during the entire season of most years, with the wet season only about half gone.

Sierra.

DELAYED BY SNOW.—*Nevada City Herald*: At the Idaho mine, near Alleghany, there are three feet of snow. The superintendent has a job of grading to do for the new hoisting works, and the snow is delaying the work.

In the Ruby mine, Sierra county, a very rich ledge has been struck which shows well in free gold.

John Fessler has bonded his mine at Chippis Flat for 60 days for the sum of \$30,000.

The Gold King has a five-foot ledge which is paying well.

Sonoma.

TAKING OUT QUICKSILVER.—R. E. Lewis, one of the principal owners of the Mount Jackson mine, southwest of Healdsburg, informed the *Tribune* that the operations continue on an extensive scale, there being 45 men on the payroll. Last month the production exceeded that of any previous month, and 154 flasks were the yield. The prospects for a continuance of such an output are good.

NEVADA.

Washoe District.

SUMMARY OF COMSTOCK OPERATIONS.—Following is Superintendent Lyman's official report of last week's work in the Consolidated California and Virginia mine: "1650 level.—In our workings in and from the drift run north from the foot of the upraise which was carried up from sill floor of this level we have extracted a few tons of ore of ordinary value. The drift running north from east crosscut 1 from the drift run north from the winze (down 52 feet) at a point 40 feet north from the winze has been advanced 32 feet; total length, 166 feet; face in porphyry and clay and quartz carrying a low assay value. East crosscut 2 from the drift run north from the winze (down 52 feet) at a point 126 feet north from the winze has been advanced 34 feet; total length, 42 feet; face in porphyry, clay and quartz. The total quantity of ore extracted from the mine during the week was 48 carloads, about 46 tons, averaging \$23.14 per ton. The largest portion of this ore came from our workings in the vicinity of the winze 20 feet down. The southwest drift (the Rule drift) from the 1000 station of the Consolidated Virginia shaft has been advanced during the week 60 feet; total length, 331 feet; face in porphyry, clay and quartz of nominal value. The bearing of this drift has been changed and the course is now 41 degrees west of south."

The weekly statement of Superintendent Kervin of the Best & Belcher mine is as follows: "200 level.—The north drift which was started in west crosscut No. 3, 175 feet from the main north drift, has been extended 12 feet and work discontinued; total length, 120 feet; face in porphyry and quartz. 900 level.—The east crosscut on the north line has been advanced 15 feet; total length, 283 feet; face in hard porphyry."

Following is a summary of the operations in other Comstock mines during the past week: In the Ophir, on the 1465 level, the north drift from the west crosscut is out 72 feet and is in soft porphyry and clay. The old central tunnel has been repaired for a distance of 155 feet from its mouth. In the Mexican mine the west crosscut from the upraise above the 1465 level is out 134 feet and the face is in a porphyry formation carrying clay separations. On the 900 level of the Union shaft the Union Con. and Sierra Nevada joint north drift from the joint west drift is out 377 feet and the face is in hard porphyry and small seams of clay. The Sierra Nevada south intermediate drift in Cedar Hill is out 373 feet and the face is in hard porphyry. In the Andes mine on the 420 level the north drift from west crosscut No. 2 is extended 8 feet and continues in ore of fair assay value.

In the Hale & Norcross mine they continue stoping ore from the winze below the 1300

level, and extracted during the week 14 cars of ore assaying \$30.23 per ton per car sample and 10 cars of ore of average assay per car sample of \$19.69 per ton. In the Chollar mine they have started a drift south 200 feet north of south line on the 100 level. Are repairing the north compartment in the main shaft below 850 level. Extracted and sent to the mill the past week 104 tons of ore from the 100 level. Milled during the week 120 tons. On hand at mill 73 tons. Average battery assays, \$20.52; average car-sample assays, \$23.36. In the Potosi mine the repairs to the west drift on the 450 level are completed and a drift south has been started. The east crosscut, 300 feet south of north line, 750 level, is out 82 feet; face in porphyry. Are repairing the south drift, 930 level. At the Ward shaft the west drift from the station, 820 level, is out 465 feet from the shaft; face in porphyry. They are still retimbering the old Alpha shaft.

Kennedy District.

PAOMISNO CAMP.—*Territorial Enterprise*: Kennedy district, in Humboldt county, is said to contain numerous veins of ore carrying gold, silver and lead in paying quantities. A stamp mill is to be erected there next spring. Below the water level the ore is said to change into high-grade sulphurets. There are seven ore-producing mines in operation in the district, and the ore extracted shows an average value of \$30 per ton. Kennedy & Co. have 800 tons of this grade of ore piled up at the mine. There are about 50 men employed in the district, and about the same number are idle.

White Horse District.

NOTES.—*Wadsworth Dispatch*: The Washoe tunnel is in 50 feet.

Teams cannot reach White Horse city and residents and visitors have to foot it.

The work on the Washoe is being pushed night and day, and something will happen before long. They expect to crosscut this ledge inside of two weeks.

The east drift on the 100 level of the Jim Blains is now in 25 feet, and it is expected to cut the ledge at between 35 and 50 feet.

Ferguson District.

BIG MINING DEAL.—A Denver dispatch says: Eben Smith, general manager of David H. Moffatt's mines, returned to-day from the Ferguson district, 50 miles south of Pioche, Nev. He has concluded the purchase of a gold property for \$500,000. Moffatt and his associates will take a half interest, and propose to spend \$200,000 at once in developing the property. They will put up their own smelter at a cost of \$50,000, as the mine is 200 miles from a railroad, and transportation of ore by wagon is impracticable. Smith reports an ore vein 26 feet wide, of which six feet averages \$120 a ton. The remaining 20 feet runs from \$18 to \$50. This district is on the proposed line of the new Nevada Southern Railway, which is being built northward from Gold's station, now Blake, Cal. All reports received in Denver indicate that there is an immense amount of gold in the now almost inaccessible region which this road is intended to traverse, and the confidential agents of the big mining men are going into it. The Smith-Moffatt purchase indicates that a new bonanza region will be opened next summer. It is not likely to be a poor man's country, as the railroad may not get through for a long time, and heavy capital is needed to insure profit.

ARIZONA.

AT DOS CABEZAS.—*Cor. Tombstone Prospector*: Four men upon the Philadelphia a short time ago got out about 65 tons and milled it in the 10-stamp mill here with such a result that they took in more men, and now have seven in all mining and hauling ore, and in a few days will start up on about 100 tons more.

The Casey Bros., on the celebrated Old Juniper, are working on good ore; in fact, all the mines, where persistent work is being done, show that we have some, at least, of the precious gold.

MACHINERY EN ROUTE.—*Tucson Star*: The machinery for the new Mohawk mine at Mammoth is en route for the mine with the William Neal teams. The plant is a new process, a grinder. It has a capacity of 40 tons a day, equal to 20 stamps. The plant will be set at the old Mammoth mill, so as to be run, for the present at least, by the power of the Mammoth mill. The mill will be run as the Mammoth has, by hauling the ore from the mine to the mill. The distance is four miles. It is probable, if satisfactory arrangements can be made, that the freighting will be done by the Neal outfit.

MONTANA.

TWO BIG DEALS.—*Butte Inter-Mountain*, Jan. 18: The Anaconda Company has purchased the Ramsdell-Parrot mine for \$65,000. The sale was made yesterday. This mine is a copper producer.

There seems to be no longer any doubt of the consummation of negotiations between Hon. W. A. Clark and English capitalists relative to certain of Mr. Clark's mining interests and the properties of Smith & Kessler, including the Clear Grit and Banker lodes. The negotiations have been carried to a successful termination by Mr. A. H. Wethey.

Smith & Kessler have sold out their interests and received the cash. Mr. Clark has not sold out, but is a part of the new concern. He has received a certain cash consideration for an interest in a group of patented copper and silver claims, and in addition to this the purchasers agree to build a smelter. It is said this will be a very extensive plant—as large as the combined capacity of the four smelters now in operation in Butte. It will be of the last modern design and the mechanical part will be operated by an electric plant.

In addition to this, the various mines acquired by this new deal will be equipped with large and substantial hoisting works. It

is asserted that by next October the new concern will be employing 2000 men. Mr. Wethey will be the general manager.

At the High Ore mine ore production was commenced to-day with a large force of men. At the Green Mountain, which has been working a light force of men the past few days on account of overproduction of ore, the force was increased yesterday. Men are at work at the Wake-Up-Jim getting the engines in condition and it is expected this mine will have a force of men at work next week. The "Jim" has been idle a long time.

OREGON.

RICH POCKET.—Jacksonville Times: W. B. Flamm, who found the rich pocket near Bald Mountain, in Jackson Creek district, a short time since, has received returns from the ore he sent below for reduction through Beekman & Reams' bank. There was between \$300 and \$400 in gold, and a small percentage of silver, which, while not as much as was reported, is a nice cleanup for a few hours' work.

WORKING A DRIFT MINE.—Ashland Tidings: Swinden Bros. are working a drift placer mine near Redland, Josephine county, this winter.

Adam Clark has a new two-stamp Elsmere mill on his claim on Sam's creek, and expects to have it running within a few days.

Jack Garvin who sold his one-sixth interest in the Golden Eagle quartz mine on Williams creek to Pelton & Neil a short time ago, is preparing to resume work on one of his quartz locations on Wagner creek.

T. A. Hill, the miner who first prospected the claim known as the Golden Fleece, on which the Moody and Flanagan mill has been erected, has sold his one-fourth interest in the mine to R. P. Neil; consideration, \$1000.

Owing to the bad roads the Ashland Mining Company only got ore enough down from the mine to run the mill 12 days last month, but with that cleaned up bullion enough to pay all expenses of the mine and mill and the work on the new 600-foot tunnel. The new tunnel ought to be completed now in less than two months.

J. E. Smith & Co. are having bad luck at their quartz mill on Klamath river. The new wheel in the river which they had all ready to start the mill with this week was taken out by the freshet of Monday. There was a 12-foot rise of the river, and the wheel had to go. They mean business, however, and will proceed to put up another wheel at once.

WASHINGTON.

ON THE SWANK.—Ellensburg Capital: A company of Duluth capitalists have been working the Green Tree claim on the Swank. They have lately located a great deal of ground, including some that has been held by the Swank Bedrock Flume Company. The company, after having an examination made by an expert, bonded the Beckhorn mine, owned by Ford, Smith & Kanp, for \$24,000. They will push work on it and, if it meets their expectations, it is their intention to erect a mill on the property in the near future. This, if carried out, will mean a great deal for the camp and for the county.

Van Drake & Taylor's Machine Works.

A. J. Van Drake, the well-known expert machinist of this city, has recently associated himself with Mr. Phillips T. Taylor under the above firm name. Mr. Taylor is an experienced mechanical engineer and draughtsman whose skill will give added efficiency in conducting the varied and particular kinds of work of which this firm makes a specialty, and which consists largely of new inventions, experimental tests and the finer grades of machinery of all kinds. Van Drake & Taylor have recently moved from their old place, 203 Fremont street, to the large two-story brick building, Nos. 523 and 525 Mission streets. Their works now occupy the entire upper floor, 40x70 feet square, well lighted and thoroughly equipped with careful workmen, increased motive power and the latest improved machinery obtainable for their purposes. With these enlarged facilities, they will be able to meet all requirements in their line.

It is of the utmost importance to inventors and experimenters that their models and fine work should be placed in the hands of experienced, skilled and trustworthy men who can readily grasp their ideas and execute them with precision; who can assist them over difficulties when they arise, and who will turn out their work with dispatch and economy.

That these qualifications will be found with this firm there can be no doubt. In addition to the above, Van Drake & Taylor carry a full line of dairy supplies, their salesroom and warehouse occupying the first floor of the building. Repairing cream separators and dairy machinery will also be a special feature of their business. See the advertisement in another column.

Coast Industrial Notes.

—San Jose has begun the work of providing for her unemployed citizens. Monday 100 men were given employment on the city streets.

—The surveyors under F. G. Brooks have completed the line from a point on Owens river, Inyo county, to the Alabama hills, a distance of about 21 miles.

—A special election is called at Seattle, Wash., for February, to decide whether or not the school district shall bond itself in the sum of \$250,000 to take up outstanding warrants.

—The recent storm was particularly severe about Victoria, B. C. Such weather had not been experienced in ten years. The San Pedro wreck was swept and it was expected to split in two before the storm ended.

—Spokane broke ground Tuesday for a new \$340,000 water works dam. There were speeches, and Mayor Powell turned the first shovelful of earth amid much enthusiasm. Employment for many will be furnished in this way.

—The Interstate Fair Association was incorporated at Tacoma, to carry out the project of holding in Tacoma next fall a big exposition, to be participated in by Washington, Idaho, Montana, Oregon, British Columbia and Alaska.

—The Seattle Board of Aldermen has passed an ordinance making it a misdemeanor for any person to keep or store within the city any explosive other than ordinary black powder, unless designed for immediate use in the city. Strict regulations are also made regarding the transportation of explosives.

—The great tunnel through the Santa Lucia mountains, which the Southern Pacific Company has been boring for more than a year past, was pierced Sunday morning. It is nearly 4000 feet long, and is one of the largest and most important tunnels in this country. Four short tunnels remain to be completed.

—W. A. Clark, millionaire mining man of Butte, Montana, and owner of the United Verde Copper Company's mines at Jerome, Arizona, has placed a corps of engineers in the field to survey a line for a narrow-gauge road from a point on the Santa Fe, Prescott & Phoenix railway to his mines, a distance of 28 miles. He expects to complete the road during the present year.

—About 11:30 o'clock Saturday night, Jan. 20th, 500 tons of earth slid from a bill at North Sausalito, near the North Pacific Coast Railroad shops, causing damage to the amount of several thousand dollars. Fences, sheds and barns were wrecked as if they were cigar boxes. After falling a distance of 80 feet it slid over 200 feet, carrying with it everything it struck, and the ground adjoining the moving mass was covered with slush six inches deep.

—During the past season the Watsonville beet-sugar factory handled 65,396½ tons of beets, from which 7768½ tons of sugar were made. There is yet a large supply of syrup on hand, which may be processed next year. This is the largest tonnage of beets handled and the greatest production of any beet factory on the continent. The season of 1894 promises to far surpass that of 1893. Already the contracted acreage has reached 12,000 acres, and the enlargement of the beet factory was a necessity.

Complimentary Samples.

Persons receiving this paper marked, are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

WEEK ENDING JANUARY 16, 1894.

512,863.—FIBER SEPARATOR.—M. A. Glendard, S. F.
512,869.—FRUIT BOX.—W. T. Cottier, Los Angeles, Cal.
512,949.—DYING APPARATUS.—E. Desta, San Fernando, Cal.
512,823.—SECONDARY BATTERY.—A. Hough, S. F.
512,931.—CHIMNEY CAP.—M. Ludwig, Albany, Or.
512,781.—SHIPPING CRATE.—I. E. Marshall, Martinez, Cal.
512,840.—TOOTH MOLD.—J. R. Phelps, Marysville, Cal.
512,841.—TOOTH CROWN.—J. R. Phelps, Marysville, Cal.
512,838.—BOOM FOR DRAGS.—W. B. Pless, Stockton, Cal.
512,901.—FOLDING BED.—G. G. Richardson, Summerville, Or.
512,993.—FRESH WATER HEATER.—R. M. Scholzko, Tacoma, Wash.
512,894.—VOTING MACHINE.—J. H. Scotford, Portland, Or.
512,911.—TOOL HOLDER.—H. Shogren, Portland, Or.
512,918.—GOLD SEPARATOR.—M. Stewart, San Bernardino, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

FIBER SEPARATING MACHINE.—Milton A. Glendard, San Francisco. No. 512,863. Dated Jan. 16, 1894. This invention relates to an apparatus for separating fibre and freeing it from dust and cellulose material. It is adapted particularly to separate the fibre of the cocoanut husk from the intermediate cellulose which grows with it and by which it is surrounded and enclosed. The apparatus consists of a series of independent rotating shafts having disks with teeth or projections upon their periphery and stationary bars with corresponding projecting plates between which the teeth pass, and means for delivering the material from one part of the apparatus to the other discharging the dust and cellulose. The result is effected by the concussion of the rapid blows caused by the moving of the rotating toothed disks between the stationary plates or disks, which breaks out and strips the filling material away from the fibre by the concussion. This separated cellulose escapes through holes or slits in the bottom of the casing and the fibre is carried forward through as many sets of cleaning disks as desired till it reaches the discharge opening.

ARTIFICIAL TOOTH CROWN.—James R. Phelps, Marysville, Cal. No. 512,841. This invention relates to artificial tooth crowns and consists in manufacturing the crowns with a metal base, band and backing, the object being to provide an improved method of preparing artificial tooth crowns with the backing and base attachments in readiness to be fitted so that the teeth and attachments may be kept in stock at all times ready for application with the minimum amount of fitting. It has been customary hitherto to manufacture the porcelain crowns or fronts ready to be used and these have been kept in stock; the fitting of the remainder of the attachments has been attended to when the patient called, and he would have to wait for all the necessary work of making the attachment and connecting it. In this device the whole thing is cast and connected with the tooth so that it is in readiness to be applied at once with very little work.

DENTAL MOLD FOR TEETH.—James R. Phelps, Marysville, Cal. No. 512,840. This invention consists of a mold and flask having handled jaws with the adjacent faces recessed and adapted to receive plaster of Paris or other composition from which the mold or matrix sections are made. These are made in various ways, having a dividing plate by which the two halves of the matrix are separated and the tooth is fitted into the matrix, after the latter is prepared, and held in place so that the metal to form the metallic crown can be poured down into the sections and surround the core which has been placed in position to receive it. The same arrangement of mold and matrix can be employed for casting the base and backing upon the tooth described in the other patent here noticed.

Assessment Notices.

OCCIDENTAL CONSOLIDATED MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Silver Star Mining District, Virginia, Storey County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors held on the fifteenth day of January, 1894, an assessment (No. 15) of Ten Cents (10c) per share was levied upon the capital stock of this corporation, payable immediately in United States gold coin, to the Secretary at the office of the company, Room 69, Nevada Block, 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of February, 1894, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 14th day of March, 1894, to pay the delinquent assessment, together with the cost of advertising and expenses of sale. By order of the Board of Directors, ALFRED H. DUBROW, Secretary.

Office—Room 69 Nevada Block, No. 309 Montgomery street, San Francisco, California.

FOR SALE CHEAP.

TEN 18" diam. suction and discharge

CENTRIFUGAL PUMPS,

WITH ENGINE ATTACHED.

—Together with—

NINE UPRIGHT BOILERS, 55" diam.

—Also—

TEN FOOT VALVES, and about 300 feet

of 18" diam. STEEL

FLANGED PIPE in 4, 8 and 12 foot lengths.

This machinery is practically new, and was built specially for use as a wrecking plant. The pumps have each a maximum capacity to deliver 60 tons of water per minute. The plant will be sold very low as a whole or separately.

These pumps are suitable for irrigating purposes or under any conditions where a large volume of water is required to be moved quickly and cheaply.

For prices and other particulars, address

MORAN BROS. CO., Seattle, Wash.

MAKE YOURSELF A
MINE FOREMAN,
Superintendent, Mining Engineer (Coal or Metal), or Successful Prospector by devoting your idle hours to HOME STUDY, BY THE METHOD OF THE CORRESPONDENCE SCHOOL OF MINES, SCRANTON, PA. To begin, Students need only know how to read and write. MODERATE CHARGES. SEND FOR FREE CIRCULAR.

TUBBS CORDAGE CO.

(A Corporation.)

Constantly on hand a full assortment of Manila Rope, Isal Rope, Duplex Rope, Tarrad Manila Rope, Hay Rope, Wharf Line, etc., etc.

Extra sizes and lengths made to order on short notice.

611 & 613 Front St., San Francisco, Cal.

ADAPTED TO EVERY DESCRIPTION OF MINING AND MILLING

OFFICE AND BRANCH WORKS,

213 FIRST ST., SAN FRANCISCO, CAL.

Market Reports.

The Markets.

SAN FRANCISCO, Jan. 25, 1894.

The silver market last Monday broke in London and New York, after having disclosed a weakening tendency for several days. On the last day of 1893 the London silver market closed at 31 1/4 per ounce standard, and 68c per ounce pure in New York. Monday London dropped to 30 1/4 d, the lowest official quotation on record there, though having touched the same on June 30, 1893. The New York price Monday was 66 1/2 c, or 1 1/2 c above the lowest recorded quotation. It will thus be seen that New York has apparently held up better than London, but the latter being the ruling market makes the New York quotation in this instance merely nominal. During the past week the London price has shown a net decline of 1/4 pence and the New York 1 1/2 cents.

Copper and Lead.

These metals have shown no change during the week.

The Quicksilver Trade.

The exports of quicksilver from San Francisco by sea in 1893 were 16,571 flasks, previously given in detail. During the same period the quantities sent out of the State by rail were as follows:

From—	Tons.
San Francisco.....	473
San Jose.....	39
Sacramento.....	17

Total..... 529

The above is equivalent to 11,755 flasks, and making a total of 28,326 by sea and rail, against 24,108 in 1892. The rail shipments were principally to Nevada and Colorado.

In 1893 there were 6450 flasks sent to New York by sea. A vessel now loading for the same destination will take 1000 flasks.

The local demand for this article is very small at present, and the recent restrictions put upon silver mining have greatly curtailed the inquiry from abroad.

NEW YORK, Jan. 25.—Following are the closing prices for the week:

	Silver in— London, N. Y.	Copper.	Lead.	Tin.
Thursday.....	31 1/4 69	10 00	3 25	20 00
Friday.....	31 1/4 68 1/2	10 00	3 10	19 55
Saturday.....	31 67	10 00	3 10
Monday.....	30 1/4 66 1/2	10 00	3 10	19 75

Mining Share Market.

SAN FRANCISCO, Jan. 25, 1894.

Nothing of importance was developed in the Comstock market during the past week. The volume of trade was light and the fluctuations in prices were small, with a downward tendency. Some of the brokers whose office expenses are large are complaining, and are saying that, if business does not improve by February 1st, they will discontinue the use of the telegraphic stock indicators at or otherwise cut down the current bills.

Lower prices were the rule in the Comstock market Monday morning. In the Pacific Exchange, at the opening, Consolidated California & Virginia declined to \$3 25. At the San Francisco Board's first session the price fell to \$3 15. Afterward there were sales at as low as \$3, followed by a small reaction at 11:15 A. M. The other Comstock stocks acted in sympathy with the leading stock.

The Comstock market opened dull and heavy Tuesday morning, and in a short time went into a decline which continued up to noon. The commission brokers, who have been buying stocks on margins of from 20 to 50 per cent for customers during the last few weeks, were active sellers. Most of the purchases were made by operators who have been shorting the market. During the day, Consolidated California sold at as low as \$2 75.

The news of the boards yesterday and to-day was not of an encouraging nature.

Van Drake & Taylor, MACHINISTS AND MECHANICAL ENGINEERS, 523 & 525 Mission St., San Francisco.

SPUR AND BEVEL GEARS cut to order. PATENT MODELS and Experimental Machinery of all kinds. SHAFTING, PULLEYS and BOXES. ENGINES and BOILERS. DRAWINGS, PLANS and SPECIFICATIONS made for new machinery. JOBSING of every description promptly attended to. FINE WORKMANSHIP GUARANTEED. Also Pacific Coast Agents for the SHARPLES CREAM SEPARATORS.

PATENT Double-Acting Cornish Plunger. PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER. AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, besides doing away with 25 per cent less power. First outlay about one-third less. Suitable to any under or downrig shaft. Friction reduced to a minimum. Occupies less space in the shaft. Has been tested about a year and proved to work satisfactory in every respect. GUARANTEED TO GIVE SATISFACTION. Special attention is called to this new feature in the drainage of mines and raising water generally, by which a continuous discharge of water is produced on the up stroke and down stroke, instead of on the down stroke only, which is effected by very much less than one-half the weight of machinery now in use. When the ordinary pump becomes too small for the work it can be replaced by the new one, using the same rod and column, and doubling the discharge of water, a most important advantage in small shafts where there is not room for a larger pump. Apply to WM NANCE, Grass Valley, Nevada County, Cal.

Advertisement for Dewey & Co. American and Foreign Patent Solicitors. Established 1860. Office of the Mining and Scientific Press, Pacific Rural Press. No 220 Market St. Take Elevator No 12 Front St. SAN FRANCISCO, CAL.

Advertisement for Adamantine Shoes and Dies. Chrome Cast Steel. Cams, Tappets, Bosses, Roll Shells and Crusher Plates. THESE CASTINGS ARE EXTENSIVELY USED IN ALL THE MINING STATES and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to above conditions. When ordering send sketch with exact dimensions. Send for Illustrated Circular. Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y. H. D. MORRIS, Agent, 220 Fremont St., San Francisco. Special attention given to the purchase of Mine and Mill supplies. Stamp Cam.

Advertisement for THE RUSSELL PROCESS. For information concerning this process for the reduction of Ores containing precious metals, and terms of license, apply to THE RUSSELL PROCESS CO., Park City, Utah. THOMPSON BROTHERS, HUREKA FOUNDRY. Manufacturers of CASTINGS OF EVERY DESCRIPTION. 127, 129 and 131 Beale Street, Between Mission and Howard, SAN FRANCISCO. GAS WORK A SPECIALTY.

Metallurgy and Ores. SELBY SMELTING AND LEAD CO. 416 Montgomery St., San Francisco. GOLD AND SILVER REFINERY AND ASSAY OFFICE. Highest Prices Paid for Gold, Silver and Lead Ores and Sulphurets. MANUFACTURERS OF BLUESTONE, LEAD PIPE, SHEET LEAD, SHOT, ETC., ETC. ALSO MANUFACTURERS OF Standard Shot-Gun Cartridges, Under Chamberlin Patent.

JOHN TAYLOR & CO., IMPORTERS AND DEALERS IN ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES, ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS. 63 & 65 First St., cor. Mission, San Francisco. We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Sootifiers, etc., including, also, a full stock of Chemicals. Having been engaged in furnishing the supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price. Agents of the Denver Fire Clay Co. and for the Morgan Crucible Co., Battersea, England. Also for E. G. Denniston's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and of full weight of silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application. JOHN TAYLOR & CO.

THE BEST MINING DISTRICT On the Pacific Coast! GRASS VALLEY, CAL. THE BEST NEWSPAPER published in the district is THE TIDINGS. Daily and Weekly edition. Gives all the Mining News. Dealers in Mining Machinery and Mining Supplies will find THE TIDINGS the best medium for directly reaching the owners or managers of mines. Investors in mines will find it to their advantage to subscribe. Many mines are in successful operation, and new enterprises are being instituted and many others are in contemplation. DAILY, \$8.00 a year; WEEKLY, \$2.50, in advance. H. S. SPAULDING, Publisher

LOANS AND MINES. Loans negotiated on first-class securities. Mines and mining prospects of guaranteed value sold on working bonds. C. H. DWINELE, Grand Hotel, San Francisco, Cal.

FRUE ORE CONCENTRATOR

OVER 3200 IN ACTUAL USE.

Manufactured under Patents of April 27, 1880; September 18, 1883; July 24, 1888; and March 31, 1891.

Price of 4-foot wide Plain Belt Frue Vanner.....\$550, f. o. b.
 " " " Improved Belt Frue Vanner 800, f. o. b.
 " 6-foot " Plain Belt Frue Vanner..... 800, f. o. b.

GLADSTONE MINING COMPANY, C. J. Clark, M. E. Gen'l Supt.
 MESSRS. ADAMS & CARTER, San Francisco, Cal.—Dear Sirs: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the Frue in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to mention. In order to give an idea of the work they are doing here I will state that the ore has varied monthly from \$5 to \$20 per ton and the tailings from nothing to 80 cts. per ton. I will conclude by saying that I cannot endorse the six foot Frue Vanner too highly, and it is the only table that I would have in my mill.
 C. J. CLARK, Gen'l Supt.

SAVED

ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt. SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION. CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE (at present).....\$350 EACH,

Including Prepared Canvas Belt.

FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing OLIVER and OLIVER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94 per cent; from East ledge, * * * a saving of 32 per cent.

The concentrator runs very easy and requires but slight attention. One man attends to rock-breaker, crusher and concentrator. You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,

E. L. BAILLOU, Propr. Bailou Reduction Works.

MINE BELL SIGNALS

ADOPTED, USED AND IN FORCE IN ACCORDANCE WITH STATE LAW.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12x36 INCHES, THE MINE BELL SIGNALS AND RULES provided for in the Vourhles Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth, so as to withstand dampness, for 50 cents a copy.

Petroleum and a Tariff Duty.

California ranks sixth among the petroleum producers of the United States. The industry is growing, and the output is being steadily increased, so that in a few years it may be reasonably expected the State will surpass Colorado, and even West Virginia, as a producer. Its total for 1892 is estimated at 485,000 barrels; Colorado, 700,000; Ohio, 20,000,000; New York and Pennsylvania, 32,000,000. The market for the California wells is altogether at home. As a matter of fact, the great bulk of illuminating oil used on the Pacific coast comes from the East, about 2,000,000 out of 15,000,000 gallons consumed being refined in this State. The various wells are being worked to their full capacity, and, no doubt, as production increases the market will expand.

The Wilson tariff proposes to place petroleum on the free list; but it must be admitted that the probable action of Congress is not being regarded with more than passive interest by the petroleum interests of this State. There is a variety of opinion among the several companies as to the probable effect of the tariff, or, rather, absence of tariff. Some think it will be harmful, others not. It would seem that the threatened entrance into this market of the Peru product would arouse special solicitude for a tariff; but the other difficulties which the foreign product must encounter—so local concerns say—are so great that the tariff is but an insignificant factor. Recently published statements have been that J. W. Grace & Co. have agreed to land crude petroleum in this market at \$2.75 per barrel. There must be an error in this statement, for the Union Oil Company is said to be willing at any time to enter into a contract to furnish unlimited quantities of fuel petroleum at \$1.75 per barrel. The company has stored at Santa Paula about 75,000 barrels of the crude product, and delivers in Los Angeles for \$1.68 per barrel. The consumption of petroleum for fuel has been surrounded with such restrictions in this city that it has not an even chance to compete with coal. Only small quantities can be stored in one place. It must be underground. And altogether it has been at a disadvantage that has seriously interfered with its use. The Pacific Coast Oil Company now turns practically all its output into illuminating oil, and is able to make a profit by delivery in San Francisco at 9 cents per gallon in car-load lots.

If Grace & Co. are to enter this market, they will probably find—doubtless, they already know—that they must quote the crude product at \$1.50 per barrel, or less. It will take quite an expensive equipment to handle and store the petroleum, including tanks of large capacity, cars, wagons, offices, etc., and perhaps pipe-lines. These things involve the outlay of a deal of capital. Doubtless Grace & Co. know what they are doing. They have

already fitted out the steamer Bawmore, at considerable expense, for carrying the petroleum, and they are, of course, ready to do all else that is necessary. The result of their experiment will be awaited with much interest.

In course of an article giving advice to owners of prospects and partly developed mines, the *Plumas National*

FRANK MCCOPPIN, CHIEF OF THE MANUFACTURES AND LIBERAL ARTS BUILDING.

Bulletin very well says: Should a purchaser come around, owners should not ask two or three fortunes for prospects, thus defeating themselves and retarding the prosperity of the county. It is wiser for a man unable to develop and operate his property, to ask and receive a moderate price for his mine than to demand an exorbitant figure, make no sale and live in penury. Capitalists can afford to take chances, but the poor man is not in position to do so.

It is not yet fully settled that the miners will send delegates to Washington, to look after pending legislation of interest to California; but it is hoped that the necessary arrangements will soon be made and the delegates may start. Hon. Tiley L. Ford and Mr. Chas. G. Yale have been selected as the delegates.

Opening the Fair.

The California Midwinter Fair was formally inaugurated Saturday, January 27, in the presence of 72,000 people, and with appropriate ceremonies. It will now be open daily, Sundays included, until June 30; or perhaps the time may be extended to July 4, when the great exposition may terminate in a blaze of pyrotechnics.

It is not too much to say that the fair has exceeded all expectation. In extent, in picturesqueness, in variety and expense it is certainly the most pretentious aggregation of attractive objects ever gathered west of Chicago; and it is probably true that since the Centennial, and except the World's Fair, it is the finest exhibition seen in this country. The fair is by no means complete, or all that it will be; but the buildings are practically finished, and it can be but a short time until there will be order and precision where there is yet much confusion and irregularity. After March 1 will probably be the time to see the fair in its perfection.

The *PRESS* will from time to time present views of the fair and its chief features. We this week give photographs of two heads of departments who have done much to bring about the success already assured.

W. A. CLARK, the well-known Montana mining man, was in San Francisco a few days ago, having just returned from a trip to his United Verde copper mine in Arizona. Mr. Clark was interviewed by a local reporter on mining topics, and he gave expression to some few things that are worth repeating. In his opinion nearly all the substantial information on which to base the judgment as to the value and permanence of great mines has been acquired in the last twenty years. Before that much was conjecture and luck. Now, although luck figures sometimes in getting possession of a good mine, more depends on its management. The way of working, handling the ore, and the building of such mills as are properly required, test the judgment and skill. A man with good business qualifications, he says, is probably

more liable to succeed than any other; yet he ought to be a judge of a mine, know how to work it from a practical and technical experience, and have as definite a knowledge as possible of all these things. Mining is now reduced to a system. It is not what it once was. All of which is eminently true. Poor judgment and inexperience are the leading features of the history of mine failures. Hard common sense and experience count for as much in this branch of industry as any other.

THE Downieville *Messenger* announces that Mr. Phillip Deidesheimer has been awarded the first prize diploma and gold medal for "superior mine timbering" exhibited by him at the World's Columbian Exposition. His system of timbering used on the great Comstock lode in Nevada,

Profit in Low-Grade Ores.

While Senator Jones' 250-foot Colorado ledge story (found in another column) sounds quite expansive, there is much food for reflection in his comment on low-grade ores in California and Colorado respectively. In California gold mining is on a bread-and-butter basis, and the search for bonanzas, if it has not altogether ceased, is not pursued as persistently as it formerly was. That is to say, the experienced investor is now satisfied if he finds a low-grade body of ore of sufficient extent and accessibility. Methods of treatment are now so exact that it is possible to make large profits out of such mines. The best paying properties are generally of that character.

If we are to judge from newspaper accounts, the situation in Colorado is quite different. The search is all for bonanzas. The bigger the story the better the advertisement for a particular locality. This is what may be described as the teething period of gold mining, for there is a good deal of slobber about it. Just the other day an enterprising correspondent in a Colorado camp sent far and wide a story that ore assaying \$78,000 to the ton had been struck in a certain mine! It is the design of Colorado to attract attention and capital. It desires to develop its gold fields, of which it unquestionably has many of great merit. But the sensible investor will hardly pin his faith to any such assertions. He must have an expert opinion, and he must have confidence in the expert. He wants to see the mill returns, or he wants the ore carefully sampled. He wants to know all that it is possible to know, before he buys. It is not possible that actual results will accord with these fabulous discovery announcements. The discrepancy, where great, will result in harm.

California has gone through all the various stages of gold-mining excitements. The industry is now on a business basis and in sound and healthy condition. We believe that its example may be imitated with profit.

It is proposed to hold in San Francisco, during the Midwinter Fair—probably in June—a mining congress, to which all the western States will be invited to send delegates. Arrangements are still altogether in embryo, but at this time it seems likely that it will be one of the most important gatherings of mining men that ever occurred in the west. Papers will be read on various mining subjects, and subjects of general interest taken into consideration.

THE operation of mining machinery by electricity appears to be making certain progress on the Pacific coast. The latest instance is that of the Tomlin mine in Madera county, which proposes to transmit power from a station three miles distant, the power being supplied by a 200-horse-power Pelton wheel. The mill is at a considerable elevation, and it is necessary to raise water about 800 feet to supply the mill. This will also be done by electricity,

River Improvement Delegates Before Congress.

The California River Improvement Delegation has had a hearing before the House Committee on Rivers and Harbors, at Washington, and presented arguments why immediate attention should be paid by the government to the Sacramento river and tributaries. The committee based its claims on the broad grounds of public necessity, and, so far as we know, refrained from touching upon matters which might have aroused the opposition of the mining interests.

The position of the delegation was wisely taken, considered from several points of view. Controversy was, on the one hand, avoided; on the other, the necessities of the Sacramento, Napa creek and Petaluma creek were placed on a common basis, in that all were in need of improvement of the same kind and all wanted their proportionate share of government attention. If the debris matter had been entered into it might have been troublesome to make clear to the committee that the filling up of the Sacramento river was due to one cause, and of these two creeks to another. These are matters upon which the so-called anti-debris interest has not been able to bring about a clear understanding of the differences if they exist; and, if not in this State, where the subject is best understood, what hope of making Congress believe that the "natural wash" (so called) filled up Petaluma and Napa creeks but has totally failed to act in the most inconsiderable manner upon the Sacramento.

The proper way for the river improvement committee to regard the matter was to take it as it found it and not to trouble itself about the unsettled question of cause. If the river bed is choked up, the true policy is to clean it out and not to attempt to show that certain interests or a certain industry was the source of the mischief. The committee appears to have taken the right view, and to have addressed itself solely to the task of showing what are the needs of navigation and dependent interests.

It is proposed to ask Congress for an adequate appropriation for rendering the Sacramento river navigable between Red Bluff and Redding; for improvement of the Feather river, and for the improvement of Petaluma and Napa creeks. Regarding the Feather river Mr. Ohleyer said, among other things:

"We only wish to carry out what has already been begun in the way of improving the navigation of this river, and rely upon the reports of the engineers in charge. I would ask for the building of two dams, as whatever debris can be prevented from entering the river is in the interest of navigation. The work already done is acknowledged to have been well planned and well executed, and the people I represent would like to see it carried on. The engineers have recommended restraining works at certain points along the valley, and also the straightening of the river at Shanghai bend. I recommend cutting off the sharp point which juts out into the river at that point."

J. M. Gleaves of Shasta, speaking in behalf of the Sacramento, said that the high freight charges of the railroad company practically prohibited the development of many Shasta county mining properties. He said that if freight charges could be reduced from \$8.70 to \$2 per ton, as it would be on the river if navigation was improved, many properties could be developed. He said that while the commission would like to ask for a large appropriation, they understood the condition of the national finances and would make their demands very modest. He asked that a snag boat be sent out as far as Redding this season. He argued that if this was done people on the river would do the rest for the present. There had been no estimate made between Red Bluff and Redding, but he thought about \$75,000 would be sufficient.

It is said that the river and harbor committee has practically decided that the total appropriation shall not exceed \$11,000,000, of which California shall receive only about \$300,000. It is hoped, however, that the efforts of this committee and the committee which is to go on for the miners may secure an increase of this meager sum.

One More Gold-Saving Device.

An Oroville mechanic has joined the long list of inventors who have constructed devices for the saving of fine gold. It is built on much the same lines as others, but presents one or two features that are novel. As described in the Forbestown *Mining Era*, the dirt is dumped on a swinging platform, set on an incline sufficient, with a small head of water assisted by the swinging motion of the platform, to cause it to pass into a long, slim box, also set on an incline, which has several sets of riffles. This box has the movement of a rocker, and the dirt, as it passes from the platform, falls upon the first riffle. The gold, sand and small gravel drops through to an apron (the heavy gravel passing over) which overlaps the second

riffle, and the water and constant rocking carries the debris and what gold is not caught under the first riffle down through or over the second, and in a like manner over several others, each of which gives the gold a chance to settle. The coarse material passes out of the rocker, over a grizzly and is dumped, while the sand and gold, if any of the latter has passed the riffles, falls into another box with several departments, lined with plates. Here it is agitated by small streams of water coming in at different directions under a pressure, until all has been brought against the surface of the plates, when the debris passes from the machine.

It is claimed that no quicksilver can escape, and that the finest and lightest scale gold, not saved in the riffles, cannot escape the plates in the last box. The motion to the machine is supplied by the water before it reaches the platform, so it requires but little water to operate it—five inches being estimated as a great plenty.

The inventor intends to give the machine a practical trial on some of the surface ground near Oroville, where the gold is exceedingly fine, and if it comes anywhere near the expectations of its owner a number will be built for operation near that town.

A Colorado Invention.

The Denver papers have recently contained enthusiastic notices of an invention, by E. R. Holden, for the treatment of low-grade gold ores, and particularly for extracting gold from placers. Descriptions of the device are, unfortunately, imperfect, and are indeed not descriptions at all. It may be interesting, however, to reproduce part of what is said about the process, omitting the altogether too abundant adjectives:

The process is a solution of the problem of treating low-grade gold ores, the principle being based upon a law of nature (gravity), coupled with mechanism to take advantage of this law. It is said that placer dirt can be handled for less than 25 cents a ton, and every trace of gold abstracted from it. The great trouble in all known processes and devices heretofore used has been due to the fact that fine gold, or the gold that had an oxidized coating of iron or other solution upon its surface, was not in a condition to be amalgamated, and on account of the low value per ton of the material it has been practically valueless. The new process claims to overcome all these objections.

The process consists of a very inexpensive apparatus, thereby placing it within the power of every poor man to operate for himself, and removes the necessity of placer owners being obliged to spend many thousands of dollars to secure hydraulic pressure; and in cases where no water can be obtained still enables the owners of the placers to operate without its use, except to a very limited degree, as no water pressure of running water is required for the operation of this process.

It is interesting to notice that this invention proposes to do away entirely with hydraulic mining, and relegate the famous "giant" to a place among the relics of an "effete past."

Mr. Holden will shortly receive letters patent from Washington, and will be able to show his friends a model of his invention in a few days. He will not handle the invention himself, but will let others take it off his hands in the way of State rights.

The Denver *Mining Record* was asked to give an opinion of the invention, and it complied in the following language: "If we understand the principle of this machine correctly, it works on the gravity system, the gravel and gold being dropped into a tank of still water about 20 inches deep. Upon the principle of specific gravity the gold is supposed to part company with the silica and sand as soon as the water is reached, the gold passing through the water to the bottom of the tank in about one-third of the time required for the waste. The principle will work on coarse gold, but flour-fine gold and leaf we do not believe can be saved by any gravity principle. It will not reach the bottom of the tank as quickly as the waste matter. Experiments have proven this to be true, and we believe that Mr. Holden's machine will be a failure for saving flour and flake gold."

THE Old Dominion mine at Colville, the most important mine in the State of Washington, which has been operating steadily during the recent silver depression, has at last been compelled to close down. For a period of eight years a large force of men had been steadily employed, the monthly payroll being a little less than \$10,000. President Dennis says that not another drill will be struck nor another blast fired in the Old Dominion until silver reaches the price of \$1 per ounce in the open market of the world. It is to be feared, then, that the mine will be idle for some time.

Progress of the Precious Metal Industry in the United States Since 1880.*

By S. F. Emmons, of the U. S. Geological Survey.

A review of the conditions governing the production of gold and silver in the United States during the past decade is more difficult to make, and, at the best, necessarily more incomplete than that of any other of our mining products, for the reason that the United States Geological Survey was not allowed by Congress to include these metals in its annual investigation of the mineral resources of our country. The Bureau of the Mint, which furnishes the most reliable data as to the aggregate production of these metals, is not so organized as to be able to segregate these products by mining districts, or even by States, in a complete and accurate manner, nor to furnish such technical data as are necessary for an intelligent study of the underlying causes which have governed the variations in the product of these metals.

Gold is the only important metal that is found in great measure in the native or metallic state, and comparatively free from other metallic combinations. Silver, on the other hand, is almost universally found in nature more or less intimately combined with baser metals from which it must be separated by a relatively expensive process in order to be reduced to the metallic state. Gold, again, is largely produced from placer deposits—detrital gravels and sands resulting from the disintegration of gold-bearing rocks and veins—in which atmospheric agents have concentrated and prepared it for man's use, so that it can be extracted by simple processes requiring but little technical skill or scientific training. The reduction of silver from its ores, on the other hand, requires in most cases not only the highest degree of technical and scientific knowledge and experience, but to render available any but exceptionally rich ores involves the expenditure of large capital in smelting plants, centrally situated and with easy and cheap railroad transportation to and from mining districts and coal fields.

The history of the development of unexplored regions rich in the precious metals follows with comparative regularity certain general lines. Gold is first discovered in the sands of the streams, and if these lead to rich and readily accessible placer deposits, a "boom" sets in and results in a very rapid increase in gold production, from the fact that large numbers, not necessarily expert miners, can work at them and no great preliminary expenditure of capital is required. With the rapid exhaustion of the richer and more easily worked placers, many abandon mining altogether; others search for new fields and for the veins from which the gold has been derived, and deep mining gradually replaces placer mining. This, however, is of relatively slow development, requires outside capital, and is more dependent on transportation facilities. Production for a time falls off, and increases again with the discovery of rich mines and consequent attraction of outside capital, which itself increases transportation facilities. This increase in production is slower than that due to the discovery of virgin placers of unusual richness. The prospector, who usually gathers his knowledge of ores not from previous training, but from practical experience in the field, searches first for the more readily recognizable gold ores and only as circumstances increase his knowledge for the more complicated and obscure silver-bearing ores. This progression is illustrated in the broad general features of production of the precious metals in the United States. When Whitney wrote his *Metallic Wealth of the United States*, in 1854, the financial conditions of the world were being seriously disturbed by the almost simultaneous development of the placer mines of California and Australia, which together had added at a bound \$120,000,000 to the world's annual production of gold without any corresponding increase in the product of silver. At that time, and for many years afterward, there was "no proper silver mine" within our territory, and it is hardly to be wondered at that he considered, in the light of the world's experience up to that time, silver to be better adapted for a standard of value than gold, since it appeared to be less susceptible to violent fluctuations in its production.

The production of the precious metals in the United States during the decade 1850-60 was practically all gold, averaging over \$50,000,000 annually, and mostly derived from placers; while of the less than \$100,000 average annual product of silver the greater part came from gold alloys.

In the early part of the decade 1860-70 the gold product fell off to \$40,000,000, but increased again to \$50,000,000 toward the end, the more complicated hydraulic mining replacing placer workings, and vein mining becoming gradually more developed. The first great silver producer, the Comstock lode, was opened during this decade,

and from this and other smaller bodies of rich silver ore, whose discovery was a more or less direct consequence of its development, the silver product increased gradually during the decade from \$1,000,000 to \$10,000,000. Toward the end of the decade the first great silver ore bodies in limestone were discovered, the first smelting works in the western mountain region were established, and the first transcontinental railroad line was built—circumstances which were to have a most important and far-reaching influence upon the mining industry.

During 1870-80 the mining industry was gradually being established on a more permanent and business-like basis through the introduction of improved methods and machinery and the increase in transportation facilities. Placer mining was almost entirely conducted on the hydraulic system, which involved a considerable investment of outside capital and the concentration of the workings into fewer hands. Prospectors were turning their attention more and more to the discovery of base-metal ores whose principal value is in silver rather than gold, and which, being more likely to develop in great bonanzas like the Comstock, were hence more attractive to capitalists. Gold mining proper settled down to a comparatively regular output, but the gold product of the country was kept up by the Comstock lode, two-fifths of whose bullion value was in gold. This remarkable deposit reached the climax of its product during the decade, contributing during five years an average of \$25,000,000 to \$30,000,000 annually to the precious-metal product of the country. The silver product during the decade increased steadily from \$12,000,000 to \$30,000,000, while that of gold fluctuated between \$33,000,000 and \$50,000,000.

The opening of the decade 1880-90 witnessed the final transference of the center of activity of mining in the West from the Sierra Nevada to the Rocky mountains. The bonanzas of the Comstock lode had been exhausted, and its deeper workings were soon to be abandoned as unprofitable. The reduction in the silver product caused thereby was more than replaced by the recently discovered silver-lead deposits in limestone of the Leadville district, which, however, carried little or no gold. The ultimate importance of the discovery of these ores, and of the many similar ones since opened as a direct result of the teachings their development has afforded to the mining community, has been shown in the enormous development of the smelting industry, and the concomitant opening of coal fields and the building of railroads in every direction through the mountain region, which, in turn, have stimulated the opening of silver mines carrying mixed or low-grade ores wherever they could be found within reach of railroads.

The characteristic feature has been the increase of railroad facilities throughout the mining region and the enormous development of the smelting industry, which is thus far the highest development of technical skill applied to the extraction of the metals from their ores. It forms the final step in the progression from the rude pan-washing of the placer worker, through the Little Giant and riffle-boxes of the hydraulic miner, to the more or less complicated crushing by stamps or pulverizers and subsequent amalgamation, with or without the addition of chemicals, and aided in special cases by various lixiviation processes. But, without the aid of metallurgical processes, carried on in a scientific manner and aided by large capital, the greater bulk of the ores that have been reduced within the last decade would never have been extracted from their rocky beds.

The decade has been one of great commercial prosperity in our country. Capital has been abundant, and has gone freely into new enterprises. It is only in such times that mining flourishes; for, on account of its hazardous nature, it is the last sought by capital. On the other hand, the investment of capital in railroads and smelting plants is a permanent one, which can not be withdrawn without great loss, and which therefore encourages the investment of other capital in tributary mines to make profitable that which is already invested. It is evident at a glance, therefore, that general industrial conditions have been such as to stimulate mining enterprises during the decade, especially such as require large capital.

The Silver Question in Peru.

Sir Charles Mansfield, English Minister at Lima, in a recent report on the trade and finances of Peru, mentions that the country is materially affected by the silver question, for Peru is silver producing, and has an inconvertible silver currency, with no paper. The exchange of the sole follows exactly the current price of silver. The depreciation of the currency has been a topic which has been much discussed in Lima. A gold standard is advocated on all sides, but this solution is impracticable in a country where the government has credit neither at home nor abroad, and where the finances are in a chronic state of irregularity.

Stickney Process of Roasting Ores.

Chas. W. Stickney, of Ketchum, Idaho, has obtained a patent for roasting ores.

Claim.—1. The process of roasting ores and depositing the sulphur in a solid form by bringing steam in contact with the ore at a red or higher heat, agitating the ore, reducing the temperature of the gases, mixing them with a quantity of air sufficient for the oxidation of the hydrogen but insufficient for the oxidation of the sulphur, and combining the oxygen of the air with the hydrogen of the gases by subjecting the mixture to the action of electrical discharges, substantially as described.

2. The process of roasting ores and depositing the sulphur in a solid form by bringing steam in contact with the ore at a red or higher heat, agitating the ore, reducing the temperature of the gases, mixing them with a quantity of air sufficient for the oxidation of the hydrogen but insufficient for the oxidation of the sulphur, and combining the oxygen of the air with the hydrogen of the gases by bringing the mixture to a red heat, substantially as described.

3. The process of roasting ores and depositing the sulphur in a solid form by bringing steam in contact with the ore at a red or higher heat, agitating the ore, reducing the temperature of the gases, mixing them with a quantity of air sufficient for the oxidation of the hydrogen but insufficient for the oxidation of the sulphur, combining the oxygen of the air with the hydrogen of the gases, and spraying the residual gases with a sulphate solution, substantially as described.

Foundry Notes.

The Felton Engineering and Shipbuilding Works are constructing six 34-foot sectional Huntington mills for a mine in Mexico.

The Union Iron Works are constructing a 20-stamp mill for the Good Hops Mining Company, Riverside county. The property has recently passed into the hands of a new company—as reported in the Press—and it is proposed to develop it on a large scale. Dudley Porter, John L. Hobson and Charles W. Morse, of Massachusetts, are principal owners, and Col. John M. S. Egan is superintendent.

Among wheels recently furnished by the Pelton Water Wheel Company are the following: Four wheels to the Columbia Gold and Silver Mining Company, near Newcastle, Placer county—one for hoist, one for mill, one for compressor, one for pump; one wheel for 10-stamp mill at Gold Ring mine; one 60-horse power wheel for the San Vicente mine in Sonora, Mexico, for a ten-stamp mill; 75-horse power wheel for a coffee plantation in Guatemala, for electric light, driers, etc.; 60-horse power wheel and Gates crusher for Quien Sabs Mining Company, in Nevada City.

The California Wire Works has recently erected at the Utica mine, Angels, Calaveras county, a ropeway for the transmission of sulphur from the mills to the two chlorination works. The length of the ropeway is 1550 feet, the rope being 7-inch diameter, with a total length of 3100 feet. It is operated by a 5-horse power Pelton wheel, and has a capacity of 60 tons per day. The total sulphuret production of the mine, however, is only about 17 tons, so the ropeway is in active operation only about two days each week. The construction was under the superintendence of Mr. E. I. Parsons.

The Southern Pacific road has sent a requisition to New York for twenty-one new engines, all of mammoth design, which will be used in the passenger service in the Tehachapi, Sierra Nevada and Siskiyou mountain regions. The Southern Pacific Company designs its own engines, after which the plans and specifications for the same are submitted to the various locomotive works of this country and bids are received from the several competitors. The estimated cost of these engines is about \$250,000, and they will embrace in their construction all the recently invented features in locomotive building which have been made. The principal object kept in view in designing these monsters has been to secure the greatest amount of power and speed combined. The engines designed are, as has been stated, of exceptionally large size, as the following description will indicate: The cylinders are 19 inches in diameter, 24-inch stroke; the drivers 63 inches in diameter, with 34-inch tires. The weight of each engine loaded will be 130,750 pounds; weight on truck, 25,850; on drivers, 104,900. The engines are what are known as the 10-wheel type and will have a maximum speed capacity of 60 miles per hour.

The bids for the construction of the steam boilers in the basement and the new dome of the San Francisco city hall have been opened and found to be as follows: Contract 54, brick work—McGowan & Butler, \$42,900; J. K. Phillips, \$39,130; Peacock & Butcher, \$34,000; Wald Tharp, \$26,330; Dennis Jordan & Son, \$29,680; M. Fennel & Son, \$33,399; Riley & Loane, \$38,000; F. A. Williams, \$40,275.

Contract 55, terra cotta—A. Steiger & Son, \$105,100; Gladding & McBean, \$97,950; Union Press Brick Company, \$108,000; Constable & Hamilton, \$110,000.

Contract 56, steel and iron—Risdon Iron Works, \$110,000; T. D. Warwick, \$38,925; Ralston Iron Works, \$96,150; Western Iron Works, \$105,600; J. McMullin, \$91,900; Constable & Hamilton, \$99,000.

Contract 57, cast iron—Vulcan Iron Works, \$3816. Entire dome and tower bid—J. H. McKay, \$230,580; O'Connell & Lewis, \$221,950; Constable & Hamilton, \$253,600.

Contract 58, boilers—Atlas Works, \$4150. The Risdon Iron Works made six separate bids, as follows \$3200, \$4650, \$2660, \$3810, \$4100, \$5140. Felton Iron Works, three bids: (a) \$8950, (b) \$8250, (c) \$4250. Parks & Lacey Co., three bids: (a) \$3520, (b) \$6130, (c) \$5180; also steam-drum, \$300. George H. Tay & Co., \$4700. Monahan & Aikens, (a) \$5610, (b) \$3410.

*Abstract of a Review of the Precious Metal Industry in the United States, contained in the "Mineral Resources of the United States."

Slickens.

It is rumored that there is to be a change in the superintendency of the Suto tunnel.

The Colliery Engineer, in its issue for January contains an appreciative sketch of the late C. H. Aaron.

CALIFORNIA ranks first in gold and grapes, second in sheep and wool, third in hops, fifth in wheat, and eighth in silver.

SAMPLES of wonderfully rich gold-bearing cement and lava have been taken from the land of Joho Cardwell near Folsom.

MR. A. S. HALLIDAY, of the California wire works, has gone to the city of Mexico on business. He will be gone about two weeks.

HON. J. F. KILDER of Grass Valley is being spoken of as the Republican nominee for Lieutenant-Governor at the coming election.

MR. L. C. TRENT, of L. C. Trent & Co., prominent dealers in mining machinery at Salt Lake, Utah, has been in the city for several days.

THE number of miners who have gone into Alaska's interior this winter is smaller than in former years. No more than 150 men have gone up the Yukon.

THE Washington Aluminum M'fg. Co., Ellensburg, Wash., has issued a neat prospectus, which gives information most generally desired in regard to the enterprise.

THE Idlewild mine, El Dorado county, has decided to light its surface and underground works by electricity and to that end has purchased a 150-light outfit. The power will be supplied by a Pelton wheel.

RECEIVER SCHLEY has sold the Morning mine, located in Shoshone county, Idaho, to Charles F. Pfister, at Milwaukee, Wis., for \$175,000, subject to a mortgage and bills which will bring the amount up to \$251,000.

THE Cable Gold Mining Company has incorporated with a capital of \$1,000,000, of which \$2500 only has been subscribed. Directors—David N. Hawley, John L. Boone, P. E. McCarthy, F. N. Clark and J. L. Fields.

THE Sunset Mining and Milling Company has filed articles of incorporation in San Francisco. Directors, Ernest J. Isham, Sydney Hart, Herbert Rosenthal, Walter G. Anderson, J. C. Eubanks and James P. Sweeney. Capital stock, \$500,000.

BETWEEN Hontington and the mouth of the Powder river, Or., a distance of about 25 miles, not less than 50 miners are engaged with rocker and sluice fine-gold mining on the bars of Snake river. From \$1 to \$2.50 a day is counted as good pay.

THE first shipment of silver bullion from the new Valardea smelters at Valardea, Durango, Mexico, is en route to the refining works at Omaha, Neb. The shipment consisted of 12 carloads. The smelters at Valardea yield a carload of bullion daily.

A RUMOR has been going the rounds of Forbestown that Alvinza Hayward, several time millionaire miner, has negotiated the purchase of the Burlington mine, probably better known as the Williams' mine, situated just outside of the Forbestown limits.

THE second payment on the Hayes mines at Junction City, Trinity county, by the French syndicate that purchased the mine last fall, was made Jan. 15th, and the company has taken possession. Work will at once be begun in fitting up and preparing for the spring run.

THE following appointments have been announced at the Mint: Ewing Bowers, San Francisco, workman; P. F. Fitzgerald, Oakland, workman; Cecil Drake, Humboldt, watchman; Miss Daisy Smith, Siskiyou, adjuster; Miss Ada Rickard, San Francisco, adjuster; Miss Flora Vivian, Colusa, adjuster.

A MINER named Martin Riley had a narrow escape from death at Butte, Mont., a few days ago. He was ascending a ladder in the shaft and had reached the 450-foot level, 200 feet from the bottom, when the ladder gave way. He fell 50 feet and struck on a piece of timber and was saved from death, though seriously hurt.

MONROE THOMPSON, owner of the mine on the Swasey place, who has been experimenting on an electrical process for working ore, says the Redding Free Press, has succeeded in making the process do the work required, and will immediately erect a plant on his mine. The ore is base, but very rich. If the plant is a success, it will open up a new era in working the base ores of the country.

A DISPATCH from Port Townsend, Wash., says a chlorination vat at the Alaska Treadwell mine, Douglass island, was robbed last week of \$10,000 in gold. The robbery was committed at night and is enveloped in much mystery. As customary, water was turned on in the vat, so that the gold might separate from the quicksilver and refuse. The following morning the water was drawn off and the vat was empty.

THE T. M. & M. Co. still ship their average amount of 300 tons of ore per month, notwithstanding the low price of silver, says the Tombstone Prospector. The cyanide process experimental station with a dynamo attachment has not yet developed into successful venture claimed for it by the exponents of its merits. The properties of the company are looking well. It is not the fault of the mines, but the price of silver which is the trouble.

THE Ludwig mill was started last week as an experiment, and it was thought it would not prove successful, says the Mariposa Gazette. It was built to run by water, and an immense wheel was constructed, but upon trial it was found that the volume of water was not sufficient to run the stamps. It is therefore deemed advisable to pull down the mill and rebuild it into a steam mill. Mr. P. McElligott, one of the best mechanics in the country, is to have charge of the new work.

THE Golden Star Mining Company, recently organized, proposes to develop the Anti-Chinese mine, Tuolumne county, which was formerly known as the White Quartz mine. This mine is situated in Tuttle town district, about a quarter of a mile southwest from Tuttle town, and about 1½ miles north of the Rawhide mine, on the mother lode. In former years this mine has produced some very good rock, which was taken from surface cuts and holes promiscuously without any regard to system or practical manner of mining, as now recognized. The company under the practical management of Geo. A. Richards

proposes entering a tunnel in on the mine for a distance of 400 feet, which will open the vein at a depth of 298 feet below the surface. At this point there is at the present time exposed by surface cuts, a body of ore which in extent and value will make this property one of the many gold producers of Tuolumne.

THE old Jordan & Galena Mining Company have been forced to close their mines and mill at Bingham, Utah, because of the situation the mining industry has been placed in through legislation by Congress. In 1893 this company produced in round numbers 6000 tons of lead, 250,000 ounces of silver and 2500 ounces of gold, which sold for about \$675,000. The same production in 1892 would have given returns in sales, under the prices ruling that year, of about \$100,000 more than the company received for its ore in 1893.

JOHN P. LEONARD of Butte county, writes to a local paper as follows: 'I desire in the interest of correct history to say, that in the fall of 1857, I then being bookkeeper in the office, and H. B. Lathrop being president of the Cape Mining Claim that on a certain Sunday (date not now remembered) while the work of mining said claim was going on, went up there to see it, and while there a very rich spot being uncovered, we took up out of the natural deposit of gravel a pan full of dirt, had it

Low-Grade Ore in Colorado.

Senator John P. Jones, the silver champion, has, in common with many others who have made fortunes in silver mines, turned his attention to gold properties. He has secured a low-grade ore proposition in Colorado and proposes to develop it on an extensive scale. The Senator himself is responsible for the following statement:

"It was while in Denver," he said, "that I first heard of this new district. A man named Baker came to me there and told me about it. The gold fields are about seven miles north of Durango, in the La Plata mountains, at an altitude of 10,000 feet, and there is ten feet of snow there now. Because of this we cannot tell exactly what the country is like. The snow is too deep to do anything. However, when I heard of the quantity of low-grade quartz there I wired my brother Sam, and he went down, and while there hooded a number of claims. The story of the

ledge as told me by Baker seemed almost too big to believe. You know how anything in reference to a mine is apt to be exaggerated. Yet I have no reason to doubt the story. He reported to me that the ledge was from 200 to 300 feet thick, flat, and cut clear through the mountain. The ore was low grade, which was just what we wanted. A few years ago nobody would touch any ore unless it was rich, and the Colorado people are not yet accustomed to working low-grade ore. But here in California we got over that long ago. We found that the most valuable kind of a mine was one with ore of low grade, and the lower the better, for as we experimented we found that the lower the ore the bigger the quantity and the more apt it was to be continuous and permanent.

"This has been shown in a striking degree with that Alaska property, the Douglass Island mine, which is probably the biggest thing in the country. It has also been shown in other sections of the country, so that it has become almost an accepted fact, especially on the Pacific coast, that the lower the ore the more of it, and the more value by far of the mine.

"Well, when this man saw me and showed me his specimens and I heard his account, it at first seemed strange. But he said to me

that he was looking for capital, he wanted the right man, and, added he: 'It doesn't cost you a cent; you can go down and examine the ledge, and if it isn't all I say it is you are not out anything and you will know for yourself what it is.' He was very square and didn't want any money in any way.

"The outcome of it all was that an inspection of the great ledge was made. We found it, as near as we could judge, as he had represented it to be. It was of hard quartz and having gold apparently all through. The ledge was very solid and nearly flat, cutting through the mountain. We located about a half a mile of the face of it. The ledge was in size what had been stated, or say from 200 to 250 feet thick. Possibly in some places it might go down 100 feet, and then again to 200 feet.

"From appearances the ledge extends to the other side of the mountain, for it was learned from mining men that pieces of quartz had been found there, which indicated that they had been broken off the ledge. Besides this, gold has been found all along the La Plata river, and, from what can be learned, it must have come from this. The pieces of quartz float, when tested, were found to run \$6 a ton in gold, and none of the ledge went less than this.

"Should the ledge prove, when the snow goes off, to be what is represented, bigger mills will be required than have ever been put up before, and they can run for an endless period, for the supply of quartz is enormous."

LIEUT. A. M. HUNT, CHIEF OF THE MECHANICAL ARTS BUILDING.

washed out in a rocker, then cleaned at the office on the bank, and the gold thus obtained in that one pan of dirt weighed 104 ounces and 4 pennyweight, worth something over \$2000, and there was not a piece of gold in the lot that would weigh as much as ten cents, it being all fine scale gold."

THE company which proposes to furnish light for the towns of Amador City, Jackson and Sutter Creek—in Amador county—all within a radius of a few miles, has perfected its plans and ordered a part of its outfit. The central station is at Sutter Creek and a 125-horse power will be used. Only lights will be furnished at first in the several towns and the stamp mills in the vicinity, but it is a part of the plan also to supply power to the towns and mines. The contemplated electric road from Ione to Jackson will also secure its power from Sutter Creek.

It seems as if the cyanide process was about to establish itself upon a firm footing in South Australia, says the Mining Standard. It has already been applied with considerable success to the treatment of ores at Wadnamanga and has given a distinct impetus to the mining operations in that district, and now it is suggested that a plant should be established in a central position in the auriferous country among the Mount Lofty ranges, near Adelaide. There is abundance of material in the Adelaide hills to operate upon, and with the exercise of a little energy and good management, there ought to be money in the treatment by cyanide of vast quantities of ore which have resisted efforts made in the past to extract the gold from them with profit. The cyanide process has proved a great boon to South Africa; and, although we recognize that there is a wide difference in the circumstances there and here, we know of no reason why the process should not be extensively availed of in many mining districts throughout the colony where rich refractory stone exists in quantity, and has had to be left alone or has only been dealt with spasmodically.

Hydraulic Mining.*

A REVIEW OF THE INDUSTRY BY DR. HENRY DEGROOT.

In Eight Parts—Part VI.

The Discharge Pipe or Nozzle.—To that part of the hydraulic apparatus connected with the final discharge of the water through nozzles, various names have been applied, such as the "goose neck," "globe monitor," "dictator," "deflector," "knuckle joint," "little giant," etc.

While certain of these names are suggestive of some property, feature or other peculiarity of the machine, more of them would seem to have no special significance, although for each of these devices the inventor has claimed some peculiar merit, and not always without reason, only a few of the entire number are now much in use.

For the information of those not posted in these matters it should be explained that, in miners' parlance, the terms monitor, nozzle and giant mean all the same thing, they being applied to these several machines indifferently, and in the case of the nozzle, very improperly, as this is only an appendage of the apparatus, being only the projecting tube or nose through which the water makes its final escape. There is need for a specific name for these discharge pipes, which should designate and be confined to that portion of them by which these movements are directed and controlled, and thus the present confusion be avoided.

These pipes range from four to nine inches inside diameter, the quantity of water they are capable of discharging varying from 300 to 1500 miners' inches of water,

ground being heavy, two or more of these cross drifts are to be driven. Each arm of the main or terminal cross drift should be from 40 to 50 feet long; of the others, about 30 feet. When the bank has an extended face and only moderate depth, several parallel drifts may be run, or as many as conditions seem to require, their length being proportioned to the depth of the bank. In all cases the length of both the main and lateral drifts must be in proportion to the extent and nature of the ground to be shattered, both of which, therefore, should be carefully studied in advance. The main drift should be as small as can be conveniently driven, say three feet wide by four feet high, the cross drifts being a little larger. Sometimes instead of carrying in the main drift from the face of the bank, it is extended from the bottom of a shaft sunk for the purpose. Occasionally short drifts called "lifters" are driven at right angles to the cross drifts, from the ends and centers thereof, these "lifters" being carried back toward the face of the bank.

For blowing up shallow banks or patches of bottom gravel, shafts with a cross drift at the bottom, or having the lower part enlarged, giving the shaft a bottle shape, are employed. These are tamped and fired in the same manner as the horizontal drifts. The shaft, when the bank is not extremely high, answers about as well as the drift, and possesses the advantage of being much more easily tamped than the latter as the material used for this purpose, being that excavated in sinking the shaft, has to be simply shoveled in.

The quantity of powder usually employed on these occasions varies from 100 to 200 kegs to as many thousand,

a space between it and the roof of the drift. Sometimes a barrier of timbers is placed across the main drift at the intersection of the first cross drift prior to the former being filled in.

For several years, at first, common blasting powder was used in blowing up these gravel banks. Gradually, however, this has come to be almost wholly superseded by the use of a low-grade giant powder. For blasting boulders, trunks and stumps of trees, lava, pipe-clay, hard bottom, cement, etc., nitro-glycerin explosives are employed.

For firing the charge, both the common and electric fuse are in use. When the latter, one should be inserted for every 40 or 50 kegs of powder, as this insures simultaneous ignition and complete combustion of the powder, whereby its entire force is usually developed. The firing is usually accomplished by means of a high-tension electrical machine placed at a safe distance from the mine and connected with the insulated wires.

The Derrick.—For handling the larger boulders, a derrick, operated usually by a hurdy-gurdy wheel, is employed. When, as occasionally happens, a boulder is encountered too large to be raised by the derrick, it is broken up with nitro-glycerin or giant powder into fragments so small that the derrick can lift them and swing them around out of the way, some of these machines having a lifting capacity of ten tons or more. The larger class of these structures have a mast 100 feet high and a boom 92 feet long. The mast is supported by guys of one-inch wire rope; a whip-block with $\frac{3}{4}$ -inch steel rope being used for hoisting tackle.

The guys, six in number, are held by double capstans. Where the derrick is to be moved but a short distance, as a hundred feet or two, this is usually accomplished with wooden rollers and without being taken down.

The Rule Drift.

Dan de Quille, a well-informed writer on Comstock mines and mining, has just published a long article on the old bonanza find in the Con. Cal.-Virginia mine, in the *Salt Lake Tribune*. He closes with the following remarks about the Rule drift, which will interest many:

The ground on which Mr. Rule proposes to search for a missing bonanza lies between the great ore body found in the Con. Virginia and the first bonanza in the Ophir, that in which the first discovery of silver was made by Peter O'Riley and Pat McLaughlin, in 1859. When this bonanza was first opened it was the wonder of the world. It was immensely rich, both in silver and gold, at the very surface. At a depth of 180 feet, at what was called the third gallery, it showed a width of 45 feet of ore, and at the fourth gallery there was a solid body of ore 66 feet in width. At the time, so great a width of ore was unprecedented.

The ore of this bonanza was exceedingly rich. No ore was shipped to San Francisco that assayed less than \$1000 a ton, and the "low-grade" ore reserved for milling in the reduction works of the company, in Washoe valley, averaged \$200 to \$300 a ton. The bonanza, wastefully as it was worked, yielded over \$20,000,000. But, as already stated, it pinched out at a depth of about 500 feet.

Undoubtedly the formation of this surface bonanza was the result of the operation of the same natural forces through whose activity was formed at a point 1800 feet below in the vein of the great Con. Virginia bonanza. Now, as the mineralized vapors and metallic emanations from the heated metals in the fiery depths near the lower part of the earth's crust must have ascended through this blank space of 1800 feet in the vein, the mystery is how it happened that no ore was deposited in any part of it.

To the southward on the Comstock lode, in the Gould & Curry, Hale & Norcross and other mines, no such extensive barren space was anywhere found between the first or upper bonanza and the next one below on the dip of the vein. There is one great cause of the existing suspicion that a bonanza has been missed in the blank space between the Ophir bonanza and that in the Con. Virginia.

Another reason for suspecting the existence of an undiscovered bonanza in this piece of ground is that it lies between two fertile sections of the lode in the line of the usual trend of Comstock ore chimneys, which is a little to the southward in descending; therefore it would seem that there can be nothing unfavorable as regards the mere rock formation. Besides, where Mr. Rule proposes to set to work is in the vicinity of the place where the first feeders of the big bonanza were found.

Many instances that might be given in mining experience go to show that a drift or crosscut may almost touch an ore body without finding it. Had not the Ophir bonanza first been discovered on the surface, a tunnel run into the mountain such a way as to have cut the vein at a depth of 500 feet would have found it pinched out, and it would have been pronounced worthless, whereas just above lay \$20,000,000.

Whether or not Mr. Rule deceived himself when he sup-

Giant Playing on Caved Bank.

according to size, pressure, etc. They can throw an effective stream on a gravel bank 200 feet away. Frequently as many as four, and even five, of the largest sized machines are played in a single pit at the same time, each machine discharging from 1500 to 1700 cubic feet of water per minute. Notwithstanding the force of one of these large jets of water, so indurated or so tenacious are some portions of the gravel to be washed that it has to be shattered with powder preparatory to playing the water upon it. The force of a large stream of water as it issues from one of these nozzles is hardly less than that of a cannon ball at the instant of its discharge. When operated the machine is brought as near the bank as is compatible with the safety of the pipe man, in order that the full effect of the jet may be obtained. When the bank is very high fatal accidents sometimes occur through its sudden caving. When much over a hundred feet in height the bank is piped off in benches as a safeguard against accident caused by these caves. The manner of piping off a cave is shown in the figure.

When it is said that a full set of the largest of these machines, as we sometimes see them operating in the hydraulic mines, is capable of performing the work of a thousand men, the remark is to be understood in a literal sense.

Bank Blasting.—When the material to be piped off is so hard or so tenacious that it cannot be readily broken down and disintegrated by the stream of water thrown upon it, recourse is had to powder for accomplishing that end. So, too, when the gravel bank is dangerously high, it is to be blown up with powder. The preliminary work required for this purpose consists in running suitable drifts under the bank to be blown up, charging the same with powder and laying the fuse, after which the main drift is to be thoroughly tamped. This drift is run in on the bottom from the face of the bank, a distance proportioned to the height of the latter and the nature of the deposit to be blown up, the quantity of powder used being determined

by the same conditions. As a rule, the length of the main drift should be about three-fourths the height of the bank, if this be considerable. From the inner extremity of this drift a cross drift is driven each way, forming a "T"; or, if the quantity of powder to be used is very large, the each keg containing 25 pounds. The minimum quantity required varies from 16 to 20 pounds for every thousand cubic feet of ground covered by the drifts; small blasts, other things being equal, require more powder in proportion to the ground than large ones. Thus, if 500 kegs of powder will break up from 40,000 to 50,000 cubic feet of gravel, 1000 kegs may be expected to reduce 120,000 cubic feet to a like condition. It is calculated that a successful blast will prepare double the area of ground covered by the drifts. As nearly as can be estimated there should always be enough powder to thoroughly shatter the bank, an excess being better than a deficiency. Two-thirds of the powder used be placed in the terminal cross drift, balance in the other cross drift. Where the drifts are dry the powder may be emptied in long boxes, or be left in the kegs, their heads having been removed. If there is water in the drifts or shafts the powder must be put in water-tight boxes, the lids being pierced with holes to admit the fuse, which, having been introduced, the lids must be fastened on firmly and the holes closed with wax, putty or other substance impervious to water.

After the boxes or kegs of powder have been placed in rows and covered with paper, the electrical wires are extended along them. The exploders are inserted in giant-powder cartridges and extended along on top of the paper covering the powder. The wires laid in the lateral drifts are then connected with those extending along the main drift to the electrical battery. If fuse is to be used for exploding the charge, it is here properly put in place—for the sake of greater security two or three lines being laid. In the center a layer of heavy rock is placed, forming the basis for the filling in or tamping, the material removed in excavating the drift being employed for this purpose. It should not be too damp, and, if present, all very large stones should be thrown out, as they may cause serious damage and perhaps injury to persons should a "blow-out" occur. Sand and fine gravel make the best tamping material. The tamping, jammed in with wooden rams, should be thoroughly done so that it will not settle, leaving

*This article was prepared by the late Dr. De Groot for the Eleventh Report of the State Mineralogist, just issued; but its publication with that of much other valuable matter was prevented by the necessity of revision and omission, so that the volume might be reduced to reasonable limits. It covers familiar ground, but is, on the whole, a complete and careful review of the industry and hydraulic-mining methods. The article has been furnished this paper by State Mineralogist J. J. Crawford.

posed he had cut into a before unknown body of ore, most mining men will agree that it is well worth while to give this particular piece of ground the benefit of more thorough exploration than it has yet received. There are in it brilliant possibilities.

The Era of Nickel Steel.

Extracts from Paper Read before the Colorado Scientific Society, Dec. 4, 1893, by W. L. Austin, Ph. D.

Attention had long been directed to the unusual properties displayed by meteoric iron, both in regard to its extraordinary toughness as well as in some instances to its non-corrodibility. Again and again during the present century investigators appear to have returned to this subject in examining the physical qualities of these celestial visitors and by endeavoring to produce artificially similar alloys. Meteoric iron is never pure, but is invariably associated with nickel and other elements, and the desirable qualities attributed to it are ascribed to this fact. It became clear at an early date that iron alloyed with nickel differed materially from the pure metal, but certain obstacles were encountered in bringing these metals together, and even when this was effected the results were far from corroborating each other. Faraday experimented in this direction by melting horseshoe nails and pure nickel together in various proportions, reaching finally only contradictory results. Berthier also made some alloys of the two metals, producing a mixture corresponding to that of a meteoric iron found near Bogota. In 1861, Loogmaid patented (British patent No. 1863, A. D. 1861) some alloys of iron and nickel, but used only very small amounts of the latter metal. Liebig examined the same subject in 1832. Mr. Fairbairn, in 1858, recorded the results of some experiments on alloys similar in composition to meteoric iron, and Boussingault, as well, investigated the subject in connection with researches on metallic meteorites, which, in fact, seem to have been the incentive that urged on all early investigators of these alloys.

But all efforts to manufacture a commercially valuable alloy of iron and nickel were in vain until a few years ago, the trouble being that the tremendous influence of minute quantities of other accompanying metals and metalloids was not understood nor suspected. It is strange that the effect of impurities on the alloy should have been unappreciated for so long a time.

Kunzel, in his report on the Vienna Exposition, speaking of the experiments made in 1860 at the Liege cannon foundry, in which it was aimed to improve the quality of ordnance metal by the addition of a little nickel, says the result was negative, and declares he cannot understand what qualities of the iron (roheisen) or nickel warranted the undertaking. Even Ledebur himself has predicted that the new nickel-steel alloys belong to that class of inventions which crop up at intervals, finally to be buried in oblivion because of their impracticability.

Probably the first appearance of nickel-iron alloys in the United States was when Philip Thurber of Detroit, at the New York Exposition in 1853, exhibited some products of the iron furnace at Marquette, Michigan. This iron was made from a nickeliferous limonite and possessed some remarkable qualities, but it was not until 1888, after experiments had been made first in France with crucible nickel-steel alloys, and subsequently in England with similar mixtures produced in the open hearth, that the subject was brought in general notice.

In May, 1889, Mr. James Riley, at the request of the Iron and Steel Institute of Great Britain, read a paper at their meeting in Glasgow, in which he set forth the results of the experiments he had been making with nickel-steel. Riley had been over in France, at the invitation of Marbeau, for the purpose of looking into the claims made for certain crucible nickel-steels by that engineer, and having satisfied himself as to their genuineness he returned to his works in Scotland and began experimenting with similar material, using an open-hearth furnace in the place of the crucibles employed in France. The results obtained by Riley are given very fully in the proceedings of the Iron and Steel Institute. Notable among them was one nickel-steel alloy containing 4.7 per cent nickel, which showed an elastic limit of 28 T. per square inch and a breaking strain of 40 T. per square inch, whereas similar steel, without the nickel, showed only 16 T. and 30 T. respectively. The elongation and contraction of area of this steel were, moreover, not materially impaired.

In August, 1890, the papers stated that the United States Naval Board was about to test "a newly-invented nickel-steel plate" recently purchased by the Chief of the Bureau of Ordnance from the Creusot works. On September 18th and 22d this plate was tested at Annapolis, Maryland, together with other representative armor plates submitted for trial, to ascertain which style of protective armor was the best for use on the new United States men-of-war then building. At these competitive armor trials the victory

rested with the French nickel-plate steel, as against another carbon-steel French plate, and a compound one of English make. On September 26, 1890, a bill was introduced and immediately passed by the House of Representatives appropriating \$1,000,000 to enable the Secretary of the Navy to purchase nickel ore and nickel mattes for armor manufacture. It appeared to outsiders as though the authorities were acting with undue haste in the matter, and immediately stories began to circulate detrimental to the new material, suggesting the possibility of a "job" lying at the bottom of the hasty action on the part of Congress. It was stated that the new steel became exceedingly brittle when subjected to great cold; that its magnetic properties were such that ship's compasses, under certain conditions, could become totally deranged; in fact, that the new product was very unreliable and uncertain in its behavior. It appeared as though experience with alloys of iron and nickel on the part of experts had been for too long a period of a doubtful nature to admit of an opposite opinion being hurriedly reached.

Mr. Tracy, however, who was at that time Secretary of the Navy, decided to have very careful tests made of this armor before adopting any kind in the new navy, and proposed to employ for such test plates that were to be made of American material by American mills. As a result of this decision, orders were given to the Bethlehem Iron Company and to Carnegie of Pittsburg to prepare such plates, the Government furnishing the necessary nickel for the work.

Shortly afterward Mr. W. L. Abbott, of Carnegie, Phipps & Co., in reporting to Mr. Tracy the progress in the manufacture of nickel-steel plates at the Homestead works, near Pittsburg, showed samples taken from some of the material out of which the trial plates were being manufactured, and which had been rolled down to three-fourths inch for experimental tests. These gave an ultimate tensile strength of 100,000 to 102,000 pounds per square inch, with an elastic limit of 59,000 to 60,000 pounds. The elongation was 15½ per cent, with reduction of area of 29½ and 26½ per cent respectively at fracture.

The toughness of nickel-steel is very great. During a visit which the writer made to the Bethlehem works last spring, a large field was observed which was covered with blocks of nickel-steel that had been cut off during the process of manufacturing the armor plates. Many of these ingots weighed several tons. They had been set out in the open field adjoining the works because it was said that no profitable method of breaking them up into sizes suitable for returning to the furnaces had yet been devised. Attempts had been made to blast them with dynamite, but the explosive shot out of the holes as from a cannon, doing little execution on the blocks. Another illustration of the toughness of the metal is given in the late experiments by the German Government, where shells were exploded in cannon, the one of ordinary gun steel, the other of nickel-steel. The former was badly damaged, whereas the latter was only enlarged.

One by one the objections raised against nickel-steel have been removed. The effect of cold weather on the plates was experimentally demonstrated to be of no importance, and in April, 1891, the first nickel-steel plates of American manufacture began to arrive at the Washington Navy Yard for testing purposes. Plates of all descriptions, with and without nickel, were exhaustively experimented with. High and low carbon steels were shot at; plates just as they were rolled or forged, and others which had been surfaced hardened (Harveyized) were again and again subjected to the fire of the most formidable modern ordnance made, rifles as high as 12-inch caliber being used. These tests extended all through the summer, fall and winter of 1891 and 1892, and are still in progress, a plate being taken for testing purposes from each lot of material delivered by the works. The results have demonstrated beyond all doubts the superiority of nickel-steel for armor purposes. The tough, tenacious material flows under the impact of the shot, and in the case of the "Harveyized" plates, the extreme hardness of the exterior surface, reinforced by the tough, untreated steel behind, shatters the forged steel Holtzer projectiles, which have hitherto proved irresistible.

Corrosion of Pumps in Copper Mines.

The Montana Society of Civil Engineers held its annual meeting in Helena last week. Mr. C. W. Goodale, superintendent of the Gagnon mine in Butte, addressed the society in regard to the matter of the corrosion of iron pumps and columns caused by the presence of sulphuric acid in the water pumped from the Butte mines. He stated that in the Gagnon mine there is considerable water constantly leeching down through the old stopes, and in so doing it seems to become impregnated more or less with sulphuric acid, which acts on the columns and pumps.

"There is quite a difference in the character of the water

in the different parts of the mine. The silver mines do not have water that is particularly troublesome, but in the copper mines there is a great deal of trouble. In the Gagnon mine we have very troublesome and corrosive water. Four years ago it was not causing any particular trouble. We often used it for boiler feed, but found that its action on the mud drums made it necessary for us to discontinue using it for that purpose. It was still giving us no trouble in the pumps and columns; but as time went on and the mine was opened up there was more of this low-grade ore for the water to leech through, until the present year has brought us face to face with the necessity of using something besides iron for the columns.

"Two and a half years ago we put in a seven-inch column to throw this water to the surface, and for awhile it showed no particular corrosive action; but during the last spring a corrosive action on the iron was very apparent, and the surprising thing about it is that this action shows first at the top of the column. As it went on more leaks occurred, until one length of pipe consisting of 15 feet had 13 clamps. I was fully determined that we must use something besides iron, but just what ought to be used is a serious question. There is one copper column in the mines in Butte, but copper is so expensive that it is almost out of the question for us to think of duplicating that column. There is also a brass column five inches in diameter, but I understood there is some objection to that. I think it is probable that we will have to come down to using iron pipe lined with wood, which is the cheapest method I know of keeping the water away from the iron."

Forestry in the United States.

The report of the Executive Committee of the American Forestry Association shows that the work of the association is beginning to bear fruit, as may be seen from the following abstract of reports recently issued by the association:

Not only has the policy of reserving public timber lands for forestry purposes, established by the last Administration, been recognized by the present Administration, in reserving some 4,500,000 acres more (the Cascade Range and Ashland Timber Reserves in Oregon), making the total acreage in forest reservations nearly 18,000,000, but there is ground for hope that some rational legislation for protecting and utilizing these reserves may be enacted. Members of the association and all friends of forestry are requested to urge upon their representatives the passage of House bill No. 119 as a first step toward a more rational use of the public timber lands.

While the action of the President and the assurances of the passage of such legislation are encouraging as committing the Government to a sound forestry policy, we have grounds for encouragement in other directions. The devotion to forestry of a special building and the creation of a special department of forestry at the Columbian Exposition are signs that our subject is permanently established, and the action of the Exposition authorities has done much to widen the circle of those who appreciate our endeavors. The special meeting of the association at Chicago, under the auspices of the World's Auxiliary Congress, has been hopeful in the same manner, and was successful especially in impressing the representatives of the lumber trade with the legitimate aims of the association and the need of its work for the benefit of the lumber interests.

The president of the association is at the head of the U. S. Department of Agriculture; one of our former secretaries is in charge of the public timber lands at the General Land Office; and the Chairman of the Public Lands Committee in the House of Representatives is fully persuaded of the necessity of new legislation along the lines urged by the association; and there is a realization that virgin forest resources have shrunk so as to expose as childish the cry of "inexhaustible" supplies, and the knowledge is at last dawning on the irrigators of the West that "the forest waters the farm," while there is a general awakening of public interest in the forestry movement, which purposes to turn the irrational destruction of a great national resource into a rational husbandry of the same.

The provisions of the bill mentioned above are extremely simple. Protection of the forest reservations (now comprising nearly 18,000,000 acres) is sought by the employment of the army, which has done such effective work in both the Yellowstone Park and Yosemite reservations. The Secretary of the Interior is empowered to make such rules and regulations and establish such service as will insure the objects of such reservations, namely, to regulate their occupancy, to utilize the timber of commercial value and to preserve the forest cover from destruction. He is also empowered to have cut and to sell timber on non-reserved lands under the same regulations as made for the forest reservations, provided that it shall be first shown

that such cutting will not be injurious to the forest. The plan is endorsed by officers of the American Forestry Association, and is hereby recommended for support and propaganda by all friends of the association.

The Slocan, B. C., Mining District.

Wm. Meadows in *Spokane Mining Review*.

I will offer a few observations in a general way in regard to this country and what we are doing in the way of mining. Every one says—miners, prospectors, practical mining men, experts and men who never saw a mine—that, "so far as surface indications go, it beats anything they ever saw in this or any other country." I will join the crowd, and state a few facts from which my conclusions are drawn.

The formation (geologically) I consider most favorable to metalliferous deposits, especially of this kind (galena) belonging to the older stratified rocks, and made up of argillaceous schists, slates and limestone of a more or less crystalline and shaley character, of a dark color and on the whole rather a soft formation, penetrated by eruptive dikes and intrusions. The general trend of the strike is north-west and southeast, and all dip to the southwest at various degrees to nearly vertical. The mineral veins occur in all manner of forms, from bed with strike and dip of strata to a cut at right angles. This mineral belt in a general way is surrounded on all sides by metamorphic and igneous rocks; on the south and west by granite; on the east by schists; on the north by different eruptive rocks.

This belt, so far as I know of valuable deposits being discovered in this immediate vicinity, may be embraced in a diamond or oval about 20 miles in long diameter, extending from the mouth of Four-mile creek (which empties into Slocan lake) northeast to McDonald's group at the head of Lile creek (a north tributary of Kaslo river), and about 12 miles wide, extending from the head of Twelve-mile or Big creek (a south tributary of Kaslo river) northwest to North Carpenter creek, on Slocan lake side of the divide.

These lines are drawn diametrically across the country. Our ores are high grade, being chiefly clean argentiferous galena, carrying from 100 to 500 ounces silver and 50 to 85 per cent lead. Picked specimens assay several thousand ounces of silver, but they are not to be seriously considered. As a fact, ores carrying less than 100 ounces can scarcely be handled at a profit at the present cost of transportation, as it costs upward of \$25 per ton to get the ore from the mines to Kaslo, the present shipping point, and then the boat and railroad transportation according to destination of ore. The greater part of this cost will be saved on the completion of the railroads now under construction. The Nakusp & Slocan Railroad connected with the C. P. R. have their grading work about completed to Three Forks (a central locality in this district), and the road will doubtless be pushed to completion as soon as navigation opens in the spring to enable them to get in necessary material. The Kaslo-Slocan R. R. Co. are clearing right of way on their road, and intend to put in their trestles and bridges this winter to avoid the hindrance of high water next spring, and expect to have their road in operation by the middle or latter part of next summer. There are now being shipped from the mines 20 to 25 tons of ore daily that will average upward of 150 ounces silver and from 50 per cent up of lead. When we remember that there was not even a pack-trail into this country until but little over a year ago, nor a prospect hole ten feet deep up to that time; and when we see that there is not yet a mill, concentrator or piece of mining machinery of any kind in the country, we are inclined to drift into speculating on the future. We severely felt the financial depression—in fact, were nearly swamped, country and all, for a time, as a great many had taken bonds on properties and made considerable cash payments who found themselves unable to lift bond or test the value of the property, and a great many of these claims still remain in the hands of prospectors. In fact, but comparatively few mines have as yet actually changed hands; but we do not expect this state of affairs to last. Capital cannot afford to overlook or neglect this country, nor will it do so. And even now, although the country is under from three to four feet of snow, we hear of new deals being made, new mines starting work and frequently hear inquiries for mining property. I have spoken of the ores as being a clean high-grade galena (carrying an unusual amount of silver and free from gangue); and so they are, so far as have been handled and generally speaking, but there are lower grade properties that will require concentration, and some of the mines—the most productive so far—have large quantities of lower or second grade ores that will not pay to handle as they are, but would turn out a good grade of concentrates at about three into one. As a further exception, I may mention that in the northeast part of the above defined territory, embracing the country between Fish and Bear lakes and North Carpenter creek, there is a promising dry ore belt from which fine samples of gray copper and

silver sulphide ores have been taken. Again, in the northern part in what is called Whitewater basin, it has been reported that auriferous quartz has been found in places in which native gold was plainly visible, and from which high assays of gold was had, but of the certainty, extent or value of which I am not prepared to speak. But few of the mines, if any, are scarce past the stage of prospecting development. I feel safe in saying there is not a shaft 200 feet deep in the camp, and but few of the mines employ over six or eight men at actual mining, as they are not yet in shape to furnish working room for a larger force.

Among the mines that have shipped more or less ore are the Washington, Mountain Chief, Noble 5, Freddie Lee, Bluebird, Dardanelles, Idaho, Cumberland, Northern Bell, Wellington, Slocan Star, Lucky Jim, Paine, Miner Boy, Big Bertha, Lucky Boy, Rico, Whitewater and others, the names of which I do not remember, and many of the most promising properties are not included in the shipping list. Some are waiting for the railroad and others are held by prospectors and men unable to do the necessary preliminary work. I am sorry that I cannot give the exact production of each mine and the value thereof, but I have not that information at hand, but will say there has been upward of three thousand tons of ore shipped at a value of over \$500,000. Considering our embryotic state and the reverses we have met, we call this a fair showing; and when we realize that we are actually shipping ore at a good profit under present difficulties, including high tariff on lead, low price of silver and high rate of transportation, we feel that we are destined to live and prosper. Taking everything into consideration, we think it beats anything we ever saw. I would say to those contemplating a move to this country that muscle at present is somewhat in excess of demand, but capital will find a wide and promising field for operation.

Mining Dividends in 1893.

The San Francisco *Bulletin* of recent date contains a review of mining dividends for 1893 from which the following is taken:

The Alaska-Treadwell paid \$375,000 last year. This includes a bonus dividend of \$75,000 last July. Our record for the Idaho is \$105,400. The property was sold to the Maryland people last spring, and most of the dividends were from the proceeds of such sale and the surplus on hand at the time of such sale. The official report of the Kennedy mine is \$460,000 for the fiscal year ending December 1st. The Great Western is credited on our book with \$37,500 in three dividends. We have only seven dividends for the W. Y. O. D., making \$21,000; five for the Champion of \$50,000; five for the Morning Star of \$24,000; nine for the Mayflower Gravel (including an extra) of \$90,000; one for the Mt. Diablo of \$15,000, and three for the Standard Con. of \$30,000. The Coptis paid one of \$10,000 in October. We have a total of \$3,742,960 by 57 gold, silver, copper and quicksilver mines in this country in 1893. Apportioned among the States, these dividends may be distributed as follows:

	Mines.	Amount.
Alaska.....	1	\$375,000
Arizona.....	1	300,000
California.....	13	1,114,460
Colorado.....	13	2,402,000
Idaho.....	3	490,000
Michigan.....	2	2,120,000
Montana.....	7	873,000
Nevada.....	6	208,500
South Dakota.....	2	210,000
Utah.....	5	660,000
Totals.....	56	\$8,782,960
1892.....	84	11,702,800
1891.....	102	16,929,800
1890.....	73	13,485,400
1889.....	75	12,210,400
1888.....	68	13,532,000
1887.....	66	10,480,700
1886.....	58	10,088,100
1885.....	53	8,290,600
1884.....	64	9,462,700
1883.....	50	10,150,200
1882.....	64	13,308,100
1881.....	60	13,563,400

The amount for 1893 is the smallest in many years. Of course the total does not cover all the dividends paid by all the gold, silver, copper and quicksilver mines in the country, but this has never been the case in the totals for previous years. So the comparison is just as accurate, so far as it goes, as if all mines were covered. It is known that there are several mines in this State that divide up something in the way of profits every year among their owners, of which the public is not advised. The famous Utica mine in Calaveras county is one of that order. The Kennedy mine in Amador county paid dividends in 1892, but did not report any, whereas it reported \$460,000 in 1893. Despite these irregularities, it is lamentably true that the mining dividends of 1893 were much smaller than for the previous year. The great falling off may be traced to Colorado, Michigan, Montana, Utah and South Dakota. The single Alaska mine paid \$75,000 more than in 1892. We have \$68,000 more from Arizona, but the total was credited to a single mine, whereas four mines were in the dividend list of Arizona in 1892, including \$140,000 from

the Copper Queen. We think there must have been dividends from other Arizona mines last year.

In 1892, fourteen California mines paid \$704,500. If the Kennedy had been included that year, as it ought to have been, the amount for the State would have been about the same as in 1893. Colorado reported \$3,176,800 from 25 mines in 1892. The great depression in the price of silver accounts for the lessened number of dividend mines in that State in 1893, and for the falling off of \$774,000 in the amount of dividends. The Mollie Gibson alone paid \$470,000 in 1892 than in 1893, but this was nearly offset by the Cleopatra, which was not in the list in 1892. The property was opened in April, 1891. The mine is near Pitkin. Last May it was predicted that there was ore in sight for two years. The Colorado mines paying dividends in 1892, but uncredited in that way in 1893, are the Adams, American Gold, American Nette, Anaconda, Argyle, Best Friend, Boston & Colorado, Bull Domingo, Clay County, Cook's Peak, Farncomb Hill, Hope, Lexington, New Gunston, Poorman, Limited, and Realto. These omitted mines paid \$550,685 in 1892. The new Colorado mines of 1893 are the Cleopatra, Pico-Aspen, Trinity Hydraulic, and Victor.

The dividends from Idaho are \$128,000 larger than in 1892. The DeLamar mine alone increased its dividends \$178,000. The Red Cloud paid \$60,000 less. But the Cœur d'Alene paid \$30,000, against \$20,000 for the Helene and Frisco in 1892.

The five copper mines of Michigan paid \$990,000 less than in 1892. Instead of the usual four dividends of \$500,000 each from the Calumet & Hecla, as in 1892, that mine paid only two of that character in 1893—one in May and one in September. The Franklin paid \$40,000 less and the Osceola \$50,000 less. The Murray paid \$100,000 more. There was no change in the amount paid by the Tamarack. The low price of copper and the general business depression last year made these copper dividends the smallest in several years. The total for 1891 was \$3,540,000.

Montana suffered more than Colorado from the silver depression, though her people made less fuss about it. The mining dividends of Montana fell off 50 per cent last year, the amount paid in 1892 being \$1,695,375 by twelve mines. Six of the mines that paid in 1893 also paid in 1892, together with the Hope, which did not pay in 1892. The six of 1892 omitted in 1893 are the Bannister, Granite Mountain, Helena & Victor, Jay Hawk, Moulton and Pandora. These six mines paid \$717,375, including \$500,000 by the Granite Mountain, which has been the leading disburser for some years. That mine paid \$1,400,000 in 1891. Up to the suspension of dividends in July, 1892, it had paid \$12,120,000. These dividends were suspended because the pay ore gave out. Before the payment of the above large amount in dividends, the mine was at one time on the point of being abandoned, and orders to that effect had been issued; but ore was found in time to prevent their execution.

Three of the mines of Nevada that paid dividends in 1892 also paid in 1893. These were the Coptis (or Young America South), Cortez and Dexter. Three that paid in 1892, but not in 1893, were the Eureka Con., Jackson and Nevada. Three that paid in 1893, but not in 1892, were the Con. New York, Mt. Diablo and Richmond Con.

We do not recall a mine in New Mexico that paid a dividend in 1893, and only one that paid \$20,000 in 1892.

Only two South Dakota mines paid in 1893—Golden Reward and Homestake. These also paid like amounts in 1892. There were also, in 1892, \$20,000 from the Buxton, \$110,000 from the Deadwood Terra and \$22,500 from the Monitor.

Utah suffered the most of all in the way of a loss in dividends through the suspension altogether by the Ontario mine, and partially by the Daly. The former was good for \$75,000 per month and the latter for \$37,500 per month. In 1892, eight Utah mines paid \$1,520,500, including \$750,000 by the Ontario and \$450,000 by the Daly. Four other small mines paid \$45,500 in 1892, but only one of these was represented in 1892 by \$5000. The Centennial increased its dividends from \$75,000 to \$187,500 and the Horn Silver from \$200,000 to \$230,000. The Mercur was a new mine with \$50,000. Dividends in a number of California and several other mines were:

Interesting Mining Decision.

The following interesting decision has just been rendered in the Superior Court for Siskiyou county by Judge Beard, in the case of J. E. Randles, plaintiff, vs. James Coggins, defendant.

This action was brought to determine the right of possession to certain placer mining ground, situated on the south fork of Hungry creek, in the Cottonwood mining district, said county and State. The plaintiff claims to be entitled to the ground in controversy under a placer location. The defendant makes a like claim, and to the same ground as that embraced within the plaintiff's alleged location.

The facts in this case, material to the issues presented by the pleadings, are substantially as follows:

The ground has been claimed and worked, as a mining claim, prior to the time at which either of the parties to this action assert or make any claim to the same. For the purposes of this action, both parties concede that at the time at which they severally claim the same by right of location it was vacant mineral land belonging to the United States, and open to exploration, occupation and purchase under the laws of the United States governing the occupancy and disposal of the mineral lands.

The defendant went upon the ground in controversy on October 20, 1893, established his residence thereon and commenced mining operations. After working about ten days the defendant made inquiry to ascertain if the ground was vacant, and, in pursuing investigation in this direction, examined the records of mining claims in the office of the County Recorder. Upon becoming satisfied that the ground was subject to location, he returned to the premises in controversy on the third day of November, 1893, for the purpose of properly asserting his claim to the ground and locating the same, by making the boundaries thereof, etc. The plaintiff, in the meantime, and on said third day of November, and before defendant had perfected his location, blazed out the lines, established corners and put up a notice on the ground, claiming the same by location, and had said notice recorded in the office of the County Recorder of the said county.

At the time that plaintiff went upon the ground for the purpose of locating the same, he knew that the defendant then resided upon and was engaged in working a portion of the ground covered by his (plaintiff's) claim of location.

The evidence discloses the facts that the defendant originally went upon the ground for the purpose of appropriating it for mining purposes, and that he, in all things, acted in good faith in the premises. The plaintiff has done no work upon the premises, and has not, in fact, done anything other than to locate the ground.

This action was commenced on the eighth day of November, 1893, and an injunction order was then obtained, and immediately thereafter served upon the defendant, restraining him from performing other or further acts on the premises. The defendant did not mark upon the ground, or establish the lines of his claim, until about the eleventh day of November, 1893.

There is no evidence in this case that there is now in force in the said mining district any local law, custom, or usage, requiring that notice of a mining location be posted on the ground or recorded, or that the exterior boundaries of the land claimed shall be marked on the ground. There was testimony to the effect that mining notices were received by the County Recorder from all parts of the county for record, and that the same were recorded in books kept for that purpose.

This evidence does not, however, establish the existence of local regulations, requiring the posting or recording of a notice, or marking the boundaries. As between these parties the question, then, presented for determination is, which of the two is, in contemplation of law, the prior locator, and entitled to this ground under the mining laws of the United States.

A party who, without complying with the requirements of law or local regulations, goes upon mineral lands belonging to the United States and relies exclusively upon his possession or work, is not entitled to the possession of the same as against one who subsequently peaceably locates a mining claim covering the same ground, and in all things complies with the Federal laws and district regulations. *Horsewell vs. Ruiz*, 67 Cal. 111, and see cases there cited.

It is not necessary that a party intending to locate placer mineral land actually discover valuable mineral therein before making such location. The location is valid without such discovery: *Gregory vs. Pershbaker*, 73 Cal. 109.

The object of notice of location of a mining claim "is a temporary protection of the claimant while the other acts of location are being performed, including the marking of the boundaries of the location. Under the law of Congress, distinctly marking the location upon the ground so that the boundaries may be readily traced is necessary, and is the main act of original location. All

such acts as are designed to afford a temporary protection to the claimant in the location of a mining claim should receive a liberal construction." *Donahue vs. Melster*, 88 Cal. 121.

A recorded notice only gives information of such claims as are at the time actually located. And a location on the ground does not give information of a claim unless it appear that the party posting the notice is, with reasonable diligence, proceeding to mark the boundaries of the claim indicated in such notice: *Gregory vs. Pershbaker*, supra.

"As between two persons, neither of whom had done any work before the attempted location, the issue must be determined by reference to priority in the statutory designation, on the surface of the limits of the claim." But in determining the question of priority in the particular referred to, says the Court in the case last mentioned, "it may be possible that the person doing the work in the ground, and who has indicated by his acts his intention to perfect a location under the mining laws and statutes, should be held, by proper application of the doctrine of relation, to have marked the boundaries of his claim, in legal effect, as against one who, for the purpose of depriving him of the benefit of his work, or of his discovery of mineral of value, shall intervene and mark the boundaries before the first occupant shall have completed, or even commenced their alignment."

True, in that case the Supreme Court did not pass upon this question, inasmuch as it was not distinctly presented by the findings. The language therein used by the Court may be considered as *obiter dicta*; and it never has been regarded that general *dicta* are considered as establishing the law in cases turning on special circumstances. The language employed by the Court as to the proper application of the doctrine of relation in the location of a mining claim, comes with such force as to lead to the conclusion that when this point is fully and fairly presented, argued, and considered by the Supreme Court, it will be declared an absolute proposition and established rule of law. If a liberal construction be given to the Act of Congress, then in legal effect, he is prior in time who first goes upon the ground, begins work therein, indicates by his acts his intention to perfect a location under the mining laws, and local regulations, where such exist, and within a reasonable time aligns and marks the boundaries of his claim.

Benevolent statutes of the United States, passed in the interest and for the benefit of its own citizens, inviting and encouraging them to occupy the public lands should be liberally construed, and in such manner as to lend full protection to the settler or appropriator: *Silver vs. Ladd*, 7 Wall, 219.

"The Code establishes the law of this State respecting the subjects to which it relates, and its provisions and all proceedings under it are to be liberally construed, with a view to effect its objects and to promote justice." Sec. 4, C. C. P.

In this case it was only about 20 days from the time at which the defendant first went on the ground until he finally completed his location by making the exterior boundaries of his claim on the ground. In the meantime he was proceeding in good faith to ascertain and establish his right thereto, and as required by law. During which time plaintiff stepped in, claimed the ground, and took the steps indicated by the law to locate the same. The Court is of the opinion that the facts in this case show that the defendant is entitled to recover as against the plaintiff. The counsel for the defendant will draw findings in keeping with the views of the Court herein expressed.

J. S. BEARD, Judge.

Cyanide in the Black Hills.

Much interest has been manifested in the recent establishment of a cyanide plant in the Black Hills. The *Deadwood Times* has obtained the following data of the initial run from T. L. Taylor, secretary of the company, about two weeks since: 34 4-10 tons of ore were crushed to 20-mesh size and the pulp leached with 18 tons of solution containing one-half of one per cent of cyanide. Six hours were occupied in forcing it through the pulp, 18 hours in leaching, and 6 more for the gold and silver solution to pass over and through the zinc shavings in wooden boxes or troughs. These shavings, on which the gold and silver had settled, were then treated to a sulphuric acid bath in a large lead tub, which destroyed the zinc and left a residue of black powder containing the precious metals. This powder was then subjected to an intense heat in the refinery furnace, the result being 33.88 ounces of bullion, showing an extraction of 93 per cent of the assay value. The ore, previous to treatment, assayed \$20 gold and 70 cents silver per ton. This recovery of 93 per cent surpasses all previous records of any mill operating under the process. At the Mercur mill, in Utah, the first run showed a recovery of but 37 per cent. Each succeeding run improved, and it is now saving from 90 to 95 per cent.

Another thing about this initial run of our local mill is the small per cent of cyanide lost. The vats are all new, the bed consisting of gravel, cocoa matting and canvas, through which the solution had to pass to reach. The ore must have absorbed considerable, as did also the new wooden boxes in which the zinc shavings were placed. Yet, with all this absorption, the solution showed but a loss of 1 8-10 pounds. Another tank containing 42½ tons of pulp is now being leached, a longer time given the solution to more thoroughly decompose the zinc before removing the product to the refinery. The bullion from this will be recovered Sunday, and it is expected the loss of cyanide will yet be further reduced. In another vat in the mill are 12 tons of prepared ore from the White Swan mine, on Squaw creek, which will be leached in a few days. No more will be crushed until the new rolls are in place; with three sets the capacity of the plant will be 50 tons per day. The management says that the phenomenal success of the method justifies the statement that in the near future the Black Hills will have the largest and most complete mill in the world using the process. They have already expended over \$125,000, all but \$17,000 in this vicinity, the latter amount being paid to the MacArthur-Forrest people for the right of using the process, and \$5000 more will be paid them to-day for the same purpose. In addition to this the local company has to pay them \$1 per ton royalty for every ton treated. The process in itself is inexpensive, but with such demands for its use it has been found necessary to fix a rate of \$10 per ton for treatment.

Tuolumne Drift Gravel.

Abstract from Article in *Tuolumne Independent*.

Of late years the above class of mining seems to have been sadly neglected, whereas in former years hundreds of miners found therein most profitable employment. We cannot perceive the cause. The dead river beds of Table Mountain are certainly not worked out, neither is there a scarcity of water for sluicing purposes. It must be that the old drift gravel miner is gone—many dead; others, after having made a stake, taken to other pursuits—ranching, pocket mining, etc. The small claims have merged into company holdings, so that the individual miner finds it more difficult to get hold of the ground to mine on. Yet many of the company holders of these auriferous lands would be willing to sublet on a small percentage if sought after. It is a much surer class of mining than that of pocket hunting, but, perhaps, not quite so exciting. In the former, a man is pretty sure of making fair wages at every wash up, whereas, in the latter a man may spend years and barely get the color, yet he works on most stochically year after year, often getting hopelessly in debt.

It is our advice to those unsuccessful pocket miners—hie you to the Table Mountain, make up a party of say two to four men, lease some of the patented gravel mines, or take up an abandoned mine, stick together, open up your mine and you will surely do well. Now, for instance, the gravel will run from a foot or two to six feet; say it pays about 2½ cents per pan of 20 pounds. It takes 137 pans to make a cubic yard, which will give an average yield of \$3 45 per cubic yard. One man should break from one and a half to two cubic yards per diem, in easy ground, which in dollars will give him for his day's work \$6.90. Reduce this one-half, say one and one-half cents to the pan, he will then make \$3 45; allowing for his water hire, he still makes small wages daily. This last figure is very poor for drift gravel. If the gravel is six feet in depth, he can make good wages, even at the lowest figure, to say nothing about the crevices in the hard bottom of bedrock where the coarse gold is found. The bulk of the fine gold is generally found on the sides or the banks of rim rock; if the bottom is a soft open slate it will be found well down in it. Again, the rich streak is often found on a false bottom of pipe clay, or some sedimentary deposit. But the gravel miner keeps his pan at work and so traces his pay dirt. As a general thing, it does not take much timber to work these mines, as a cement floor is generally found above the gravel; so a few stulls is all that is needed, or a pillar of gravel can be left in places to steady the worked-out ground. Then all the large boulders or heavy rock should be thrown back into the worked-out blocks and filled in, which keeps the ground secure.

The proper way to work drift gravel mines is to first have an accurate survey made of the river bed and run your crosscut tunnel under the bed of gravel; tap the gravel by raises from the main tunnel, which is drifted up and down stream. This relieves your mine of the water. Your mine is dry, the water so much met with is used in the sluices to wash up your pay dirt. It is a mistake to sink for drift gravel; that may be one reason why gravel drift mining has fallen into disrepute. Many mines have tapped the gravel beds too high, hence they have to sink and must then contend with water, which must be pumped out or hoisted by bucket; hence it takes a much higher grade of gravel to pay for the labor extracting it.

Scientific Progress.

Origin of Anthracite.

The main difference between anthracite and bituminous coal is that the former is devoid of volatile matter. Heretofore, the theory generally accepted to account for this difference was that presented a half century ago by Prof. Rogers while conducting the first geological survey of Pennsylvania. Observing that the anthracite beds lay in the eastern part of the State, in close proximity to the Archean axis of elevation, he surmised that these coal beds had, so to speak, been "coked," upon the elevation of the Appalachian chain; that is, he supposed that the heat and pressure accompanying the Appalachian elevation, acting most vigorously near the axis, had distilled and removed the volatile matter of the coal beds nearest it.

To adjust the theory to increasing facts, Prof. Lesley added the supposition that the heat involved in this theory was brought up by conduction when the superincumbent layers of rock were extremely thick, which have since been mainly removed by the erosive agencies which have been active over the region for millions of years.

The inadequacy of these theories has led Prof. J. J. Stevenson, of the University of New York, to propound another and simpler theory, which was ably defended by him at the recent meeting of the Geological Society of America.

He would account for the lack of volatile matter in anthracite coal by the simple fact that it had been longer exposed to that kind of decay which takes place in vegetable matter when immersed in water, and which consists chiefly in the loss of hydrocarbons which constitute the volatile elements in bituminous coal. On this supposition, the anthracite beds are those which were formed earliest in the swamps and lagoons of the carboniferous period, and remained longest devoid of the covering of sedimentary deposits which subsequently preserved them from further change.

This theory is confirmed by the fact that there is no such strict relation of the anthracite beds to the Appalachian axis elevation as Prof. Rogers had supposed, and by many other considerations which Prof. Stevenson is about to publish. This simple cause seems adequate to account for all the phenomena, and probably solves one of the long-standing mysteries of geological science.—From the Independent.

A Recent Report on the "Grip."

It is about four years since the epidemic influenza began its ravages in this country, having been originally imported from Europe; and, having become domiciled, it has now entered upon its fifth season of mischief in the United States, although, fortunately, not with the same severity that has characterized its previous prevalence, says the *New York Tribune*.

An official report on this malady by medical officials connected with the Local Government Board of Great Britain has recently made its appearance. Therein the existence of an influenza bacillus is reaffirmed. Dr. Klein says that this microbe "is always abundantly present in the bronchial secretions of patients," and "diminish in number as the disease is abated." The germs are disseminated, according to Dr. Parsons, by bringing the affected and healthy together, as in public vehicles and places of meeting, and especially by the poison being present in confined and vitiated air. Dr. Caldwell Smith says: "An individual is affected by breathing at once the expired air from a person suffering from the disease, and I believe this to be the only method of infection." Numerous stories are told to show how the malady is carried from place to place. A music teacher visited two relatives

who were victims of it, and three days later was himself attacked. However, he made a round of his pupils before succumbing, and two days afterward ten of them also developed the disease. The ordinary intercourse of a household or business office, letters written and sealed by sufferers, finger account books whose leaves have been turned with moistened finger-tips by affected persons, and riding in close and crowded railway cars, are among the most common methods of propagation.

Isolation of patients, disinfection of rooms, and ample ventilation are strongly urged as preventive measures. At Brighton, the inmates of the borough sanatorium were protected effectually by such precautions as these for two successive seasons, and during a third season the only case was that of a servant returning from a distant place where the disease was prevalent. When she fell ill she was promptly isolated, and thus no one else was affected.

Action of Oxygen in Asphyxia.

With regard to the physiological action of oxygen in asphyxia, more especially in coal mines, a committee of the British Association has arrived at the following conclusions:

1. In the case of rabbits asphyxiated slowly or rapidly, oxygen is of no greater service than air, whether the recovery be brought about in an atmosphere contaminated by carbonic acid or completely free of carbonic acid, and whether artificial respiration be resorted to or not.

2. Pure oxygen, when inhaled by a healthy man for five minutes, produces no appreciable effect on the respiratory rate and volume, nor on the pulse rate or volume.

3. Oxygen, whether pure or somewhat diluted, produced no effect on one particular patient, who suffered from cardiac dyspnea of moderately severe type, in the direction of ameliorating the dyspnea, and, compared with air inhaled under the same conditions, produced no appreciable effect, either on the respiratory rate and volume or on the pulse rate and volume.

4. An animal may be placed in a chamber, the general cavity of which contains about 50 per cent of carbonic acid, and retained there for a long time without superintention of muscular collapse, provided a gentle stream of respirable air gas or oxygen, indifferently, be allowed to play upon the nostrils and agitate the surrounding atmosphere.

The Earth's Motion Made Visible.

In the December issue of *Popular Astronomy*, Eliza A. Bowen shows how the earth's revolution may be made manifest to the eye. Dr. L. Smith, in *Popular Astronomy*, says: Place on the floor of a room free from tremors and air currents a good-sized bowl nearly filled with water, and sprinkle over the surface of the water an even coat of lycopodium powder, and across this make a narrow black line of pulverized charcoal. Place the bowl so that the black line shall coincide with a crack in the floor; or, if the room be carpeted, lay a stick upon the floor exactly parallel with the mark. After a few hours it will be found that the line is no longer parallel with the stationary object, but has moved from east to west, proving that during this interval the earth has moved from west to east.

The reason appears to me to be that the solid floor has, with the earth and bowl, moved from west to east, and so has the water also, but at a slower rate, as there is a slight inertia, of which the yielding liquid does not instantly partake, to be overcome. It will be seen that the line or charcoal mark always moved from east to west.

INVENTORS, TAKE NOTICE!

L. PETERSON, MODEL MAKER,
226 Market St., N. E. cor. Front (up stairs) San Francisco.
Experimental machinery and all kinds of models, tin and brasswork. All communications strictly confidential.

NOTICE TO MINE OWNERS!

The undersigned will have in operation at the Midwinter Fair a complete free gold and concentrating plant, where they will work, free of charge, any lots of ore from one to five tons.

For further information address them at 213 First Street, San Francisco.

F. A. HUNTINGTON.

EASTERN PRICES BEATEN.

San Francisco Pioneer Screen Works

JOHN W. QUIOK, Proprietor.

IMPROVED FACILITIES, FINEST WORK, THE LOWEST PRICES.

Perforated Sheet Metals, Steel, Russia Iron, American Plating, Zinc, Copper and Brass Screens for all uses.

MINING SCREENS A SPECIALTY.

221 & 223 First St., San Francisco.

QUARTZ SCREENS

A specialty. Round, slot or burr slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American planished Iron.

Zinc, Copper or Brass Screens for all purposes. Cal. Ironia Perforating Screen Co., 145 & 147 Beale St., S. F.

SEND FOR PRICE LIST.

THE JUDSON DYNAMITE AND POWDER CO.

MANUFACTURERS OF

DYNAMITE AND BLASTING POWDERS.

18 CALIFORNIA STREET,

SAN FRANCISCO.

Directors:

C. S. BENEDICT, ALVINZA HAYWARD, JOS. KNOWLAND, JOHN S. DOE, ED. G. LUKENS (President).

IMPROVED FORM OF HYDRAULIC GIANTS.

THE ABOVE CUT ILLUSTRATES THE IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. We latter, however, we furnish when requested. Prices, discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.

JOSHUA HENDY MACHINE WORKS, 51 Fremont St., San Francisco.

FRANCIS SMITH & CO.,

MANUFACTURERS OF

SHEET IRON & STEEL PIPE

FOR TOWN WATER WORKS.

Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.

NO. 180 BEALE STREET, SAN FRANCISCO, CAL.

Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

STAMP SHOES.

STAMP DIES.

Adamantine Shoes and Dies

—AND—
CHROME CAST STEEL

Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

THESE CASTINGS ARE EXTENSIVELY USED IN ALL THE MINING STATES

and Territories of North and South America. Guaranteed to give better and

cheaper than any others. Orders solicited subject to above conditions. When

ordering send sketch with exact dimensions. Send for Illustrated Circular.

Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y.

H. D. MORRIS, Agent, 220 Fremont St., San Francisco.

Mechanical Progress.

Making an Ax.

On entering the main workshop, the first step in the operation which is seen is the formation of the ax-head without the blade, says an exchange. The glowing flat iron bars are withdrawn from the furnace and are taken to a powerful and somewhat complicated machine which performs upon them four distinct operations, shaping the metal to form the upper and lower part of the ax then the eye, and finally doubling the piece over so that the whole can be welded together. Next the iron is put in a powerful natural-gas furnace and heated to a white heat. Taken out, it goes under a tilt-hammer and is welded in a second. This done, one blow from the "drop" and the poll of the ax is completed and firmly welded. Two crews of men are doing this class of work, and each crew can make 1500 axes per day.

When the ax leaves the drop there is some superfluous metal still adhering to the edges and forming what is technically known as a "fin." To get rid of the fin the ax is again heated in a furnace and then taken in hand by a sawyer, who trims the ends and edges. The operator has a glass in front of him to protect his eyes from the sparks which fly off by hundreds as the hot metal is pressed against the rapidly revolving saw. The iron part of the axe is now complete. The steel for the blade, after being heated, is cut by machinery and shaped. It is then ready for the welding department. A groove is cut into the edge of the iron, the steel of the blade inserted, and the whole firmly welded by machine hammers. Next comes the operation of tempering. The steel portion of the ax is heated by being inserted in pots of molten lead, the blade only being immersed. It is then cooled by dipping in water, and goes to the bands of the inspector. An ax is subject to rigid tests before it is pronounced perfect. The steel must be of the required temper, the weight of all axes of the same size must be uniform, all must be ground alike, and in various other ways conform to an established standard. The inspector who tests the quality of the steel does so by hammering the blade and striking the edge to ascertain whether it be too brittle or not. An ax that breaks during the tests is thrown aside to be made over.

Before the material of the ax is in the proper shape it has been heated five times, including the tempering process, and the ax, when completed has passed through the hands of about 40 workmen, each of whom has done something toward perfecting it. After passing inspection the axes go to the grinding department, and from that to the polishers, who finish them upon emery wheels.

Improved Brakes.

The *Railroad Gazette* says that the Pennsylvania Railroad will shortly have all passenger cars equipped with the quick-action brake, and the locomotives equipped with the automatic engineers's valve. The process of changing from plain automatic to the quick-action brake has been going on for some time. The large number of cars and engines to be changed has necessarily delayed the matter until the present time. This shows the way in which brake matters are drifting, namely, toward the most powerful quick-acting and efficient brake that can be obtained for passenger service. Perhaps this turn in brake matters is emphasized by the investigation now being made into the efficiency of reinforced brakes.

The reinforced brake has been brought out to do better work and more powerful braking than can be obtained from a quick-acting brake. It is found that in face of danger the length of stop, even with the quick-acting brake, is so great as to result in accidents, more particularly collisions. The reinforced brake is an improvement on the

quick-acting brake. It does not make the brake act quicker; it makes it more powerful during the first part of the application, while the train is running at high speed. The reinforcement comes during the early part of the application, and is reduced as the speed reduces, in order to prevent sliding the wheels. This reduction is also necessary in order that the maximum braking efficiency may be obtained, for the reason that if brakes were applied with the reinforced pressure at low speed the wheels would slide, and when the wheels do slide the retarding force is greatly decreased. There can be no doubt of the necessity of using quick-action brakes wherever possible and the reinforced brake for all high-speed trains; and it would appear, from present indications, that in the future it will be as necessary to use the reinforced quick-acting brake as an improvement on the plain quick-acting brake, as it now is necessary to use the latter in place of the plain automatic.

Water Proof Masonry.

What was at first considered a doubtful experiment, viz., the use of coal tar as a means of rendering masonry impervious to water, especially in positions exposed to direct contact with the latter, has proved a practically valuable resort. Used as a coating for masonry built up of very porous stone, tar renders it very impervious, even at a depth of some 50 feet of water, and, according to the opinion of those whose experience has been extensive with it, the article should be utilized in all public buildings, particularly those designed for the preservation of works of art, the dissolving action of water, even upon mortar of superior quality, being well known, and also the favorable effect of the exudation of water charged with lime salts from the mortar. Two methods of using the tar are named, viz., in a boiling state in one of several layers, this being suitable for surfaces exposed to the air; or it may be made to flame up before using, this being appropriate to surfaces which have to be covered up. It is stated that when boiling coal tar is employed in three coats on masonry the result is a black and very brilliant varnish, which perfectly resists the action of frost, water and sun, being likewise absolutely impervious; and the tendency of the black coating to absorb heat may be overcome by white-dusting the whole before the tar is quite dry.—National Builder.

A Twelve-Mile Gun.

In a paper read before the Western Society of Engineers, Captain W. H. Jaques says: "The wire-wrapped type had the honor of firing the 'Jubilee Rounds' in the Queen's Jubilee year, and gave wonderful results. On April 16, 1888, was fired at Shoeburyness the first of a series of rounds intended to investigate the conditions attending firing at very long ranges. The gun selected was a 9'2 gun, made under the direction of General Maitland in the Royal Gun Factories. The weight of the gun was 22 tons, that of the projectile 380 pounds, which, fired with a charge of 270 pounds, gave a muzzle velocity of 2360 foot seconds. The elevation of the first round was 40°. The projectile fell at a range of about 21,000 yards, or nearly 12 miles. On July 12, at 43° elevation, a range of 21,600 yards was attained, and on July 26, with 45° elevation, the range was 21,600, or about 12 1/4 miles. The projectile remained in the air about 69 1/2 seconds, and its trajectory reached a height of 17,000 feet, or about 2000 feet higher than the summit of Mount Blanc."

Who Invented the Lightning Rod?

It was said a little while ago that an obscure Hungarian priest was the inventor of lightning rods, and not Benjamin Franklin. Now a German Egyptologist, Herr Heinrich Brugsch, claims that he has ample proof that the ancient Egyptians used a form of

lightning rod for protecting their temples against discharges of atmospheric electricity, and that Franklin merely reinvented the same device. But, until he can prove that Franklin was aware of what the ancient Egyptians had done in this direction, the American is just as much entitled to be regarded as an original inventor.—Invention.

Useful Information.

The Loudest Noise Ever Heard On Earth.

No thunder from the skiea was ever accompanied with a roar of such vehemence as that which issued from the throat of the great volcano in Krakatoa, an islet lying in the Straits of Sunda, between Sumatra and Java, at 10 o'clock on Monday morning, August 27, 1893. As that dreadful Sunday night wore on the noise increased in intensity and frequency. The explosions succeeded each other so rapidly that a continuous roar seemed to issue from the island. The critical moment was now approaching and the outbreak was preparing for a majestic culmination.

The people of Batavia did not sleep that night. Their windows quivered with the thunders from Krakatoa, which resounded like the discharge of artillery in their streets. Finally at 10 o'clock on Monday morning a stupendous convulsion took place, which far transcended any of the shocks which had preceded it. This supreme effort it was which raised the mightiest noise ever heard on the globe. Batavia is 95 miles distant from Krakatoa. At Carimon, Java, 355 miles away, reports were heard on that Sunday morning which led to the belief that there must be some vessel in the distance which was discharging its guns as signals of distress. The authorities sent out boats to make a search; they presently returned, as nothing could be found in want of succor.

The reports were sounds which came all the way from Krakatoa. At Macassar, in Celebes, loud explosions attracted the notice of everybody. Two steamers were hastily sent out to find out what was the matter. The sounds had traveled from the Straits of Sunda, a distance of 969 miles. But mere hundreds of miles will not suffice to illustrate the extraordinary distance to which the greatest noise that was ever heard was able to penetrate. The figures have to be expressed in thousands. This seems almost incredible, but it is certainly true. In the Victoria plains, in West Australia, the shepherds were startled by noises like heavy cannonading. It was some time afterward before they learned that their tranquillity had been disturbed by the grand events at Krakatoa.—From the Youth's Companion

History of the Calla Lily.

This was first introduced to Europe from Southern Africa in 1687, and has become a great favorite with cultivators all over the world, says *Meehan's Monthly*. It does not like a very warm temperature nor a very cold one. It will live out in American waters, provided it is deep enough to be below the reach of absolute ice. It fills the ditches and narrow creeks in Cape of Good Hope, much the same as our spatterdock would here. It was removed, by Kunth, from the genus *Calla* and called *Richardia Africana*, but it is not easy to get rid of a name which once gets into general use, hence it still goes by the name of *Calla*. The spotted one, common in cultivation during the last few years as the *Richardia albomaculata*, was also introduced from Southern Africa in 1859. This is well known by its spotted leaves. Another one was brought from the same country in 1857, under the name of *Richardia hastata*—the spathe being of a yellowish color, but very small, and is not yet much known. On account of the common calla blooming most freely in the

spring of the year, it has come into general use for Easter decorations; and not unfrequently receives, with a number of other plants, the common name of Easter lily.

The Best Preservative Paint for Iron-Work.

Mr. W. Thomson recently read a paper before the Manchester Association of Engineers on "The Influence of Some Chemical Agents in Producing Injury to Iron and Steel," in which reference was made to the effects of different paints and varnishes used for the preservation of structural iron and steel from rust. From experiments made by himself, Mr. Thomson has arrived at the conclusion that red lead paint is the best preservative. This result has struck him as remarkable, because red lead is a highly oxidizing substance; but the reason was found to be that red lead had the effect of producing a skin of the unoxidizable and protective black or magnetic oxide on the iron itself under the paint. The author has also found that other oxidizing agents, such as manganese dioxide, form a paint which preserves iron from rusting; and this discovery he regards as of great industrial importance. Mr. Thomson explained that, having been required some time ago to make a considerable number of experiments to ascertain the most suitable paint for protecting a large iron structure from the action of sea-water spray and rain, he arrived at the conclusion that red lead paint was the best he could find for the purpose. Mr. John West, a vice-president of the society, who presided on the occasion of the reading of the paper, supported the statements and views of Mr. Thomson that red lead is the best preservative paint for ironwork. The chief novelty brought out in the paper was the reason why red lead is so efficient in protecting iron.

A Note About Water.

Where does all the water in the sea come from, is a question that many a small boy has asked his father, and which many a father has found himself utterly unable to answer. Some idea of where it comes from may be gathered from a glance at the following table of the hourly quantity of water discharged into the sea annually by some of the best-known rivers of the world. It was compiled by an expert and may be accepted as accurate:

River—	Million Cubic Feet per Hour.
Amazon	3700
La Plata	3100
Mississippi	2070
Volga	1120
Danube	950
Ganges	700
Nile	560
Rhine	230
Elbe	100
Seine	80
Thames	40

This, of course, throws the question back a step. The question becomes, where does the water in the rivers come from? When that is answered by the statement that it comes from the hills we have gone about as far as we can go. Water is an element, and what its original source may be no man knows.—From Harper's Young People.

Reversible Boot Heels.

An English firm has recently been granted letters patent for an invention whereby heels of boots and shoes can be easily detached and reversed. The invention consists of steel, or any similar material, shaped as a lift, with flange and groove, by the first of which it is fixed in any part of the height of the heel, at the option of the maker, while the upper portion of the heel is so constructed as to slide into position so that it is indistinguishable from an ordinary heel; but to insure absolute security a fine screw is inserted from the inside. The advantages claimed for it are that when the top piece becomes slightly worn down the wearer can reverse it to the other boot, and after these have been well worn they can be replaced by a new set at a very small cost.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved
Concentrating Belt manufactured in San
Francisco. We keep always on hand
Belts suitable for the Triumph and Frue
machines, but can make any length or
width desired. The advantages of these belts over
any others will be readily seen by practical millmen.
First, the flanges or edges of our belt stand at an acute
angle inclining toward the center, and therefore readily
conform to the change of direction while passing over
the end rollers; thus the vexation and loss caused by the
frequent breaking of the flange of the old style belt is
practically done away with. Again, our belts, at intervals
of two to four feet, have a very slight rifled surface for the
space of three inches, which tends to equalize the pulp
on the belt, and prevents it from banking on the sides and
forming channels through the center. These slight rifles
also save very fine sulphurets and the quicksilver that
would otherwise escape with the tailings from a belt,
the surface of which is entirely smooth. We can safely
say that it is a better concentrator belt than has ever
been manufactured. It will last much longer and
will handle more pulp. We also manufacture smooth belts with same flanges when desired.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist
who has devoted many years to assaying and working pre-
cious ores on the Pacific side of the American Continent.
He writes whereof he knows from personal practice, and in
such plain and comprehensive terms that neither the scientific
nor the practical miner can mistake his meaning.
The work, like Mr. Aaron's former publications ("Testing
and Working Silver Ores," "Leaching Gold and Silver
Ores") that have been "successfully popular" is written in a
condensed form, which renders his information more readily
available than that of more wordy and less conscientious
writers. The want of such a work has long been felt.
It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Ma-
terials; The Assay Office; Preparation of the Ore; Weighing
the Charge; Mixing and Charging; Assay Litharge; Systems
of the Crucible Assay; Preliminary Assay; Dressing the
Crucible Assays; Examples of Dressing; The Melting in
Crucibles; Scorchification; Cupellation; Weighing the Bead;
Parting; Calculating the Assay; Assay of Ore Containing
Coarse Metal; Assay of Roasted Ore for Solubility; To
Assay a Cupel; Assay by Amalgamation; To Find the Value
of a Specimen; Tests for Ores; A Few Special Minerals;
Solubility of Metals; Substitutes and Expedients; Assay
Tables.
The volume embraces 130 12mo. pages, with illustrations,
well bound in cloth; 1893. Price, \$1, postpaid. Sold by
DEWEY PUBLISHING CO., Publishers, No. 220 Market
Street, San Francisco.

Parts II and III.

**Gold and Silver Bullion, Lead,
Copper, Tin, Mercury, Etc.**

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and is
separate from Part I, and treats of Gold and Silver Bullion;
Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion;
Assaying Bullion; Humid Assay of Silver; Gay Lussac's
Method; Volhard's Method; Manipulation; Lead Ores; Cop-
per Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and
Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur;
Salt; Note.
One of the methods given for the Assay of Copper is new
original and exact, as is also one of the processes for Zinc.
The book contains 161 pages with illustrations, and is
strongly bound in cloth. Much of the original text is re-
placed by new matter.
Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING
CO., Publishers No. 220 Market St., San Francisco.

Electricity.

The Headlight of the Future.

Electric headlights for locomotives will probably come into general use within a few years. Indeed, it will not be surprising if some States pass a law compelling companies to substitute them for the present means of illumination. Eminent authorities agree that many collisions, involving great loss of life and property, could have been averted had the engineers been able to see more than the few hundred feet lighted by the oil reflector. Several of the terrible disasters resulting to the World's Fair special trains, just before the close of the exposition, were mainly due to this fact. The evidence brought out by the coroner's inquest after one of these accidents showed that the night on which it occurred was very dark and foggy, and that the train employees could scarcely see 200 feet beyond the engine's pilot. One of the engineers testified that if he had had a few hundred feet more space he could have brought his train nearly to a stop and greatly diminished the effect of the collision.

While several railway companies, including the Southern Pacific, are experimenting with improved headlights, the Georgia Southern and Florida is one of the first, if not the first, line in the country to use the electric light regularly in operating its trains. In a letter to the *Manufacturers' Record*, Receiver W. B. Sparks writes as follows:

"We have eight electric headlights. They cost about \$375 each in place on the locomotive. The cost of maintenance is not greater than the oil light. An old headlight will not throw its light on a very dark night more than 150 feet, and it is impossible for an engineer to slow up his train in that distance, even with the emergency brake. The electric light throws its light from one-half to three-quarters of a mile. Obstructions can be easily seen at that distance, and some of our engineers claim that a switch disk can be more easily detected by it at night than in the daytime. These lights do away with switch lights, which is quite a saving to roads that use them to any great extent.

"Railroads such as ours, running through the pine lands of the South, kill a great many cows. During our rainy season the lands along the line of road become very wet; in places they are entirely covered with water, and the cattle come down upon track seeking some dry spot on which to sleep. We have killed, when we used the old headlight, as many as 13 at one time, and our claims for stock killed per month have sometimes amounted to over \$1000. The engines using the electric headlight have never killed a cow, and I am confident that the saving in stock claims alone will more than pay for the lights within the next two years."

Electricity Defined.

Prof. Galileo Ferraris, a well-known Italian physicist, has defined electricity in clear terms. Asked what electricity is, his answer was given to the following effect:

Maxwell, he wrote, has demonstrated that luminous vibrations can be nothing else than periodic vibrations of electro-magnetic forces. The experiments of Hertz established the fact that electro-magnetic oscillations are propagated like light, and thus the theory of Maxwell has secured experimental confirmation. Out of these experiments and theories have originated the idea that either the luminiferous ether and the seat of electric and magnetic forces are one and the same thing—that, in a word, light is electricity and electricity is light. This being established, the answer to the question, "What is electricity?" becomes easy. Electricity is not only the powerful agent which occasionally tears and rends the air, shaking

the earth with the terrible thunder which marks its progress through the atmosphere, but it is also the life-giving agent which sends forth from heaven to earth, in company with beneficent light and heat, the magic of colors and the breath of life.

It is electricity which makes the heart beat to the palpitations of the external world, which gives birth on the human face to expressions of emotion, and thus has the power to transmit to the soul the enchantment of a look and the grace of a smile. This definition is poetical and fanciful, no doubt, but on the whole it describes the genesis and influence of the complex force, electricity, with more clearness than is usual with scientists.

Electricity of the Skin.

In his last published work Professor Yarchanoff, of St. Petersburg, gives the results of his researches with the electric currents of the skin. As stated, these experiments led him to connect the skin of various parts of the body by means of non-polarizable clay electrodes with Meissner's galvanometer, and at such times the various stimuli of the skin—such as light tickling with a brush, heat, cold, a needle prick, sound, light, taste and smell—were noticed, and in all these cases a strong deflection of the galvanometer needle was observed. Merely opening the eyes, after they had been closed for some time, produced a considerable deflection; and mental efforts, like calculation, also had a similar effect. These currents, if they exist, it is remarked, must pass off with the moistened deposits which are being constantly expelled and a new supply of electricity would have to be found somewhere; and such electricity, says Prof. Yarchanoff, having its source perhaps in the decomposition of metals, taken in the food we eat and the air we breathe, must of necessity entail upon the organism a continuous strain in its production, it being from such causes, perhaps, that the body becomes fatigued after a comparatively few hours of exertion, and absolute rest becomes necessary for recuperation.

To Purify Sewage.

That electricity is a giver of life has been proved by many of its recent applications to farming, etc., and that it is equally a destroyer of life has been demonstrated in a variety of ways. Its latter qualities are further shown by Albert E. Woolf, who has devised a method of disinfecting sewage by the electrolysis of sea water. At Brewsters, a small town about 20 miles from New York, it was found that sewage was percolating through a marsh into one of the streams from which New York derives its water supply. To remedy this, we are told, a steam plant of 15-horse power has been put down for purification of the Brewsters sewage. The dynamo furnishes 700 amperes at a pressure of five volts, a current amply large enough to electrolyze and thoroughly disinfect the liquid sewage which was the source of all the danger.

Telegraph Typewriter.

D. P. Kent, of St. Paul, is the inventor of a telegraph typewriter, hearing his name, which, if successful, may eventually displace the Morse system entirely. The operator plays upon the keys of the instrument, as in any ordinary typewriter, but the resulting manuscript is produced at the telegraph office or station where it is to be delivered, which may be a thousand miles away. The main advantage to be gained by this over the Morse system are three in number—more words a minute can be sent, there is no receiving operator at the other end of the line to make blunders, the one to whom the message is addressed is not left in the dark by a blindly written message, every word being produced as it was ticked off by the transmitting operator.

THE GRIFFIN MILL

The Only Perfect Pulverizer

OF
QUARTZ,
GOLD
OR SILVER
ORES,
PLUMBAGO,
PORTLAND
CEMENT,

OF
PHOSPHATE
ROCK,
FOUNDRY
FACINGS,
And All Other
Refractory
Substances.

Will work either wet or dry, and deliver a finished product. Capacity, 3 to 4 tons per hour on Phosphate Rock, 1½ to 2 tons per hour on Portland Cement, Quartz or Ores, depending on hardness of material to be pulverized and fineness of product. Grinds from 30 to 250 Mesh with equal facility.

NO JOURNALS IN GRINDING CHAMBER. BALL RIGID ON SHAFT HAVING DIRECT POSITIVE ACTION ON MATERIAL. MINIMUM POWER PRODUCES MAXIMUM AMOUNT OF PRODUCT. IT IS ABSOLUTELY GUARANTEED IN EVERY RESPECT, BOTH AS TO CONSTRUCTION AND CAPACITY. FIRST COST, WEAR, AND OPERATING EXPENSE MUCH LESS THAN STAMP MILLS. LARGE NUMBER OF MILLS IN USE ON DIFFERENT MATERIALS WITH POSITIVE SUCCESS IN EVERY INSTANCE.

Correspondence solicited, and illustrated descriptive pamphlet furnished on application to

Vulcan Iron Works,

135 to 145 FREMONT ST.,
SAN FRANCISCO, CAL.

PATENT Double-Acting Cornish Plunger.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER.
AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, besides doing away with heavy balance bobs often carrying from 25 to 50 tons of balance. Works with 25 per cent less power. First outlay about one-third less. Suitable to any under or downright shaft. Friction reduced to a minimum. Occupies less space in the shaft. Has been tested about a year and proved to work satisfactorily in every respect.
GUARANTEED TO GIVE SATISFACTION.

Special attention is called to this new feature in the drainage of mines and raising water generally, by which a continuous discharge of water is produced on the up stroke and down stroke, instead of on the down stroke only, which is effected by very much less than one-half the weight of machinery now in use. When the ordinary pump becomes too small for the work it can be replaced by the new one, using the same rod and column, and doubling the discharge of water, a most important advantage in small shafts where there is not room for a larger pump.

Apply to WM NANCE, Grass Valley, Nevada County, Cal.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Butte.

STRUCK A LEDGE.—Forbestown *New Era*, Jan. 25: It is reported that the Palo Alto mine, on the Mountain House ridge, near Merrimac, has tapped an extensive quartz ledge in a new tunnel they have been running.

It is reported that F. W. Dunn, a Nevada State capitalist, who was in Forbestown last week, secured an option upon the Denver mill and mine, owned by G. W. Price. The bond is to run 60 days, and the reported price to be paid for the property is \$24,000. The Denver mine and mill is situated in the Forbestown mining district, about 2½ miles east of the town. The mill is new, having been in operation only one month; substantially built, first-class in every particular, and has ten stamps. The ledge from which the ore is obtained is well defined, and, everything considered, is a desirable piece of property.

Mr. Dunn while here visited a number of ledges upon which work is being done, and made a careful examination of them. He seemed favorably impressed with what he saw, and will return again to make further investigations. He is a man who has had much experience in quartz mining, and is backed by capital.

The Bullion mill is about ready to commence crushing rock. This mill, as our readers know, is owned by citizens of Forbestown, and has 10 stamps. The work of building the mill was commenced about the first of December last, has been delayed by bad weather, but now everything is in place save the driving belt, and that will be in a day or two—probably before this notice is read. This company has a large amount of ore already out, and the mill will be operated to its full capacity from the start. That the ore is first-class there can be no doubt. One of the ledges from which the company will take ore is known as the Keystone. It was prospected by the Plumes-Enreka Company last summer under a bond from the then owner, Mr. Reasoner. While the company found the ledge to contain good ore, it was not of sufficient width to furnish rock enough to keep a mill the size they wished to build running. They did not wish any ledge that would not justify the building of a 40-stamp mill, therefore forfeited their bond. The ore to be first worked by the new mill will be taken from the Bullion ledge, near which the mill is built, which can be handled with but little expense.

The machinery for the new air compressors that are now being placed in the Gold Bank mine at Forbestown has arrived. The last shipment required seven wagons to haul the same from Oroville to the mine. The machinery will be placed in position as fast as possible. H. P. Stow, the superintendent, is every inch a miner, and very enthusiastic in his work, and has surrounded himself with assistants who are competent and take great interest in their work.

Sinking on the Shakespeare's new shaft is being pushed as rapidly as possible, three shifts being employed.

NEW HOISTING WORKS.—*New Era*: H. P. Stow has a force of men at work on his quartz mine in French ravine, near Hurlston. The shaft is now down 160 feet, with two levels. Hoisting works, to be run by water power, are now being put in. There is a probability that a mill will be erected shortly.

Inyo.

THE BLACK WARRIOR.—*Independent*: Tressel & Mann are at work developing the Black Warrior mine, about six miles west of Big Pine. There is a shaft sunk about 110 feet in the ledge, and at a point 60 feet from the surface a tunnel has been run 200 feet along the ledge. The ore assays about \$23 a ton all through, and is free-milling gold. The mine is about 300 yards from Big Pine creek, and there is plenty of timber all around it. The ledge is about a foot thick, has clearly defined walls, the hanging being slate and the foot granite with clay casings. There is every indication of the mine developing into a permanent and valuable property.

WORKING ON GALANA.—*Big Pine Cor. Register*: The mining outlook for this section is flattering. M. H. Bush and Supervisor Uhlmeier began operations on their galena near Alvord yesterday. Experts pronounce this to be an excellent property. D. M. Tressel and J. N. Munn, owners of the Warrior mine on Big Pine creek, have resolved on the thorough development of this claim, and will seek out the condition of the lead at a depth. Dave Pitman, J. R. Eldred and Uncle George L. Cornell left last week for their lead claims in Lead canyon, and will take out a shipment of ore. The developments at the Montezuma by J. H. Coe and Andy Fife, the persistent prospector, indicate that their faith in this celebrated property is not misplaced.

Kern.

AN OUNCE A DAY.—Of the new gold fields in Kern county, of which so much has been said lately, the *Californian* says: A brief note received from Mr. Sherman, the *Californian's* expert now investigating the desert placer mines, states that the average results secured by the miners in Redrock canyon are an ounce a day. The best reported in any day was 15½ ounces. The pay dirt lies close to the surface, and covers a wide extent of territory.

Nevada.

RAPIDLY COMING TO THE FRONT.—*Union*: The Centennial mine is now entirely clear to the 650-foot level, which is the bottom drift. A fine ledge is exposed in this level, also in the 600 and 500 levels. The tributaries at work in

the mine continue taking out some very handsome looking quartz, and will have a crushing just as soon as the roads become passable, so that the rock can be hauled to the mill.

TWENTY-FIVE MEN WORKING.—*Herald*: The impression prevails that the Champion is entirely closed. This is not true. There are still 25 men at work there—quite a respectable force.

GRAVEL STRUCK.—*Union*: James Andrews, an old-time and well-known miner, says he and his partners have struck pay gravel in the old Enreka claim which they have been prospecting on the Blue Tent road.

CLAIM BONDED.—Mr. James M. Lekanian has informed the *Union* that he and co-owners have bonded a small claim situated on Gold Hill near the Scadden Flat mine to James D. Hogue, Esq. The property is in a good locality.

Mariposa.

GOOD PLACERS.—*Gazette*: Some very rich placer ground has just been discovered above Mariposa, around the Ludwig mill. The ground there has never been worked, and it has been found to be full of flour gold.

Placer.

GOON GRAVEL.—*Colfax Sentinel*: At the Foss mine at Lowell Hill, of which Geo. Woods has charge, last week a test was made of the gravel through which the main tunnel is being driven, and it paid better than any heretofore to the running foot. At present the mine is being put into shape for drifting, and in the spring more men will be put on.

Parties at Forest Hill have leased the Homestake mine near there, and will begin work on the property again.

The dam at the Polar Star mine at Dutch Flat is being raised, and it is expected soon to proceed with the work in the mine.

The mill at the Gold Ring mine at Green valley is now ready for operation and will be crushing cement next week. Supt. Ames is an expert millwright and has had considerable experience in setting up mills. It was an extremely arduous task to bring the heavy machinery from the top of the mountain ridge on the Iowa Hill side down to the river thousands of feet below. A chute was built for this purpose and the ponderous mortars and other heavy machinery were thus taken down. It was quite a feat, and that the mill is all ready for work is due to the skill and energy of Supt. Ames and his efficient foreman, L. C. Jacobs. Over 600 feet of eight-inch pipe have been made on the ground, and nearly 700 feet of ditch dug, in order to gain the power for the mill. The Gold Ring gives every promise of becoming one of the paying mines of Placer county.

Plumas.

MINING PROGRESS.—*National Bulletin*, Jan. 25: Work at the Riverdale mine is progressing favorably. There has been some delay, owing to the difficulty of getting machinery in from Chat at this season of the year. It is expected that sinking will begin within ten days at furthest.

At the Mills shaft last week a big lot of water had to be contended with, but the machinery has proved equal to the occasion, and work is progressing as usual.

Owing to the great volume of water now in Spanish creek, the Quincy Mining & Water Co. will defer work on the big stone dam until spring. They have begun the construction of a "rock-crib" dam in Wapamsee creek, the site agreed to by the Debris Commissioners. About 15 men are now at work on this dam. When completed, behind it will be a large impounding reservoir, which will enable the company to utilize the water season in hydraulic lifting at this point. The structure will be very substantial and prevent any debris from reaching Spanish creek.

The mining outlook for Plumas county is brighter than it has been for many years past. The indications are that we shall have an early spring, which will open with unusual activity in mining circles, especially in the vicinity of Quincy. An era of prospecting and development work in different parts of the county will be inaugurated, and the county will be visited by numerous mining men in search of properties to invest in, or to develop those in which they have become interested already.

The Green Mountain mine has a number of men employed, and 25 stamps are steadily crushing ore from it. With means to develop and operate it properly, this would soon become one of the best and largest mines in the State.

Riverside.

FIVE-STAMP MILL.—*Banning Herald*: An immense five-stamp mill was side-tracked near the local station this week. It came from the defunct Temescal tin mines, where it was used for sampling. It was purchased by the Morongo King Mining Company. Another five-stamp mill with engine for the same enterprising company is en route from San Francisco.

San Bernardino.

VANDERBILT M. AND M. COMPANY.—*Shaft*: People in camp are wondering which mill will be in operation first—Campbell's or the one at the Bronze. Campbell's mill is on the ground, but when will the repairs be here? is the question. The mill for the Mining and Milling Company is liable to be here any day, and will be all ready to put up. Mr. Smith is not letting the grass grow very much on the ground that is to be graded. The sound of the shooting in which he indulges, in order to get the hard rock out of the way, sounds like a five-gun battery. The grading, which was a very hard job, is now just the same as completed. The three winzes and double-compartment shaft, which are being sunk from the lower level, will soon be down another hundred feet, and then another drift will be run to connect them, and will be at least 500 feet long. At the lowest point yet reached in the mine, the indications

are more than satisfactory, the vein taking up almost the entire width of the winze. It seems more than likely that a very large ledge will be struck a little lower down. The ore taken from the bottom of the winzes and shafts will average better than at almost any other part in the mine.

Ventura.

GOON PROSPECT.—*Venturian*: Harry Meyer has just returned from a three months' prospecting tour over in the Pirn section in the northeastern part of this county. He reports an excellent prospect in gold quartz, and says that many abandoned claims, worked years ago, are being relocated. There is a lot of gold in that section, and he thinks that it will lead to a boom. The Fraser mine is located in that same section. It has been in litigation for a long while, but is now settled. Mr. Meyer says that their tunnel has uncovered a ledge of great thickness. There is enough of this in sight to keep the ten stamps of the mill now there at work for ten years.

NEVADA.

Washoe District.

SUMMARY OF COMSTOCK OPERATIONS.—The official letter of last week's operations in the Consolidated California and Virginia mine reads as follows: "1650 level.—In our workings in and from the drift run north from the foot of the upraise which was carried up from sill floor of this level we have extracted a few tons of ore of ordinary value. The drift running north from the east crosscut No. 1 from the drift run north from the winze (down 52 feet) at a point 40 feet north from the winze has been advanced 19 feet; total length, 185 feet; face in porphyry, clay and quartz, from which a few tons of ore have been saved. The west crosscut No. 2 from the drift run north from the winze (down 52 feet) at a point 126 feet north from the winze has been advanced 32 feet; total length, 72 feet; face in porphyry, clay and quartz. The total quantity of ore extracted from the mine during the week was 57 carloads—about 56 tons—averaging \$29.85 per ton. The largest portion of this ore came from our workings in the vicinity of the winze—20 feet down. The southwest drift (the Rule drift) from the 1000-foot station of the Con. Virginia shaft has been advanced during the week 62 feet; total length, 453 feet; face in porphyry, clay and quartz of nominal value. The course of the drift continues the same as reported last week.

The weekly letter of the superintendent of the Best & Belcher mines contains the following: "200 level.—At a point in the northwest drift, 170 feet from our north boundary, have started an east crosscut, No. 3, and extended same 15 feet during the past week; face in soft porphyry. 900 level.—The east crosscut on north line has been advanced 14 feet; passing through hard porphyry; total length, 302 feet."

Following is a summary of the official news from other Comstock mines: In the Ophir the north drift from the west crosscut on the 1465 level is in 89 feet, with the face in porphyry showing clay separations. The old Central tunnel has been repaired and retimbered a total distance of 345 feet. In the Mexican the west crosscut from the south drift from the upraise, 45 feet above the 1465 level, is in 160 feet; the face is in porphyry carrying clay separations. On the 900 level of the Union shaft the Union Con. and Sierra Nevada joint north drift is in 393 feet; the face is in clay and porphyry. They have started a joint east crosscut from the south drift near the north line of the Union Con. mine. The Sierra Nevada south drift from the intermediate tunnel in Cedar Hill is in 388 feet; the face is in hard porphyry. In the Andes mine the north drift from west crosscut No. 2 on the 420 level was advanced 15 feet; the face continues in quartz. In the Gould & Curry mine, on the 200 level, west crosscut No. 5 from the northwest drift is in hard porphyry.

The official letter from the Potosi mine says: "The south drift on the 450 level is out 33 feet; face in low-grade quartz. The east crosscut, 300 feet south of north line, 750 level, is out 107 feet; face in porphyry. The repairs to the south drift on 930 level are not yet completed." In the Chollar mine the south drift on the 100 level is out 12 feet; face in low-grade quartz. Are repairing the north compartment in the main shaft below the 800 level. Extracted and sent to the mill the past week 96 tons of ore from the 100 level. Milled during the week 109 tons. On hand at mill 74 tons. Average battery assays, \$19.19; car-sample assays, \$21.13. In the Hale & Norcross mine they continue to stop ore from the winze below the 1300 level and extracted during the week 11 cars of ore assaying \$30.48 per ton, per car sample, and 21 cars of ore, average assay per car sample \$20.76 per ton. At the Ward shaft the west drift from the station, 820 level, is out 485 feet from the shaft; face in clay and porphyry. Repairs to the old Alta shaft continue. At the Alta mine they sank the 725-level winze 14 feet; total length, 22 feet; and the width of the ore continues about the same. They have saved about six tons of ore that will average \$26 per ton.

Ferguson District.

LOW GRADE ORE PLentiful.—*Pioche Record*: A number of claim owners hereabouts are anxious that the mills in the vicinity should start up. In all probability the mills will be kept busy on ore from this district from the time they drop stamps. So-called low-grade ore—that is, ore running below \$40 a ton—is plentiful, and a dozen different claims offer inducements for work if ore of \$20 could be made to pay a profit.

Nearly every claim on which much work has been done in this district shows up promisingly. One of the latest is the Paymaster, situated about a mile east of town and about the same distance north of the April Fool. Jos. Bryant and John Reese have put down a 26-foot shaft, exposing a fine face of mineralized quartz from five to seven feet in width with assays running from \$9 to \$100 a ton in gold. It is believed to

be the same mineral belt as that on which the April Fool and Monitor claims are located. The work still continues, and shipments to mill will be made as soon as the mills will receive them.

Jumbo District.

JUMBO AND WASHOE ORE.—*Enterprise*: E. W. Harris, of the Harris mine in Washoe district, says that it is reported that a rich streak of gold-bearing quartz has been found in the Smith mine, and also that rich ore has been found in the Berry mine in Jumbo district, which adjoins Washoe. The Berry mine is named after Harry Berry, a Comstock miner who has been prospecting in Jumbo ever since the discovery of that district, and while heretofore not making any important developments, has taken out sufficient ore to pay expenses. Mr. Berry is very reticent about his recent discovery, and belongs to that class of prospectors who "say nothing but saw wood."

Silver Star District.

A NEW CAMP.—Silver Star district is now attracting the attention of mining men, says the *Walker Lake Bulletin*. Old prospectors who have visited the district declare that it gives evidence of being the best camp ever seen in the county. The country is taken up for about three miles. The mines are situated between Garfield and Soda Springs, and about 30 miles east from Hawthorne. The best prospect in the district at present is being worked by Ed. Brown. The shaft is about fifteen feet deep and the ledge in the bottom is nearly five feet wide. The whole ledge will pay \$30 per ton, but it can be sorted so as to go to \$100. Wood and water are convenient, and if the ore goes down Silver Star will be a great camp.

White Pine District.

SHUT-DOWN AT OSCEOLA.—Word has been received from Osceola, says the *White Pine News*, that Supt. A. J. Millick, of the Osceola Gold & Milling Co., has closed down the mill for the winter, owing to the heavy snow and cold weather. The ores there are plentiful and easy to leach, so that those interested think the camp is going to take on new life in the spring.

ARIZONA.

FINE ORE.—*Moheve Miner*: Some of the finest ore in White Hills camp has been struck in the bottom of the shaft in the G. A. R. mine. The shaft is now down over 400 feet and a large body of water has been encountered. The pump handles this volume of water very easily, and there is no delay in sinking from this source. A. M. McDaniel has given a lease and bond on the Tennessee mine, at Chinle, to Walter S. Hadley of Albuquerque. Mr. Hadley will immediately commence work on the property and open it up in good shape. If the ore body develops well, a concentrating plant will be erected near the mine and the ore reduced as much as possible. The property is a good one, carrying a very high grade of galena with gold and silver in paying quantities.

A strong effort is being made to put up a high mill in the vicinity of Stockton Hill by Eastern parties. The development of that part of Mohave county is earnestly to be desired, because it has some of the richest mines ever found in the county. A tunnel under the hill would open up hundreds of veins, the wealth of which is incalculable.

NEW MEXICO.

NEW MINING CAMP.—A new gold field in the Black Mountain spur of the Organ range of southwestern New Mexico is attracting considerable attention. Prospectors and old timers are flocking to the scene from various parts of the country, some of them in mule teams and some afoot. Twelve and a half square miles of claims have been located, and the samples of ore promise a bright future for the camp, which is located near the Mormon mine. A small town will soon be established, and, as soon as capital becomes interested, things are expected to hum.

OREGON.

A GOON PROSPECT.—*Baker City Democrat*, Jan. 22: Three hundred and twenty-seven ounces—that is the weight of a gold retort brought in from the White Swan yesterday. After another run of six days at the White Swan, Supt. Niven is again to the front with a fine cleanup, the value of which being \$6000.

OPERATIONS RESUMED.—*Baker City Democrat*, Jan. 22: After a month's suspension on account of the replacing of the old boilers by new ones, the Virtue mine resumed operations yesterday with a large force in every department, and under more favorable auspices than ever, and it can be safely stated that the monthly outputs will be larger than ever.

BUILDING A ROAD.—*Jacksonville Times*: The Golden Eagle Mining Co. have a force of men at work building a road to their mines in Williams Creek district, in order to haul the ore to the mill, which is two miles distant. There are 75 tons of quartz on the dump, to be milled when the weather settles, and they have a prospect shaft down 80 feet.

G. W. Tremain, of Wolf Creek, has sold two stamps of the Star mill to M. E. Clark & Son of Leland, who shipped them to Gold Hill, where they will be placed in operation.

J. Garvin has commenced work on one of his quartz locations on Wagner creek, having disposed of his sixth interest in the Golden Eagle mine, on Williams creek, to Pelton & Neil.

Owing to the bad roads, the Ashland Mining Co. only made a 12-day run last month. The new tunnel will be completed in about two months, as the Burleigh drill is doing good work.

Hull & Beck, who have rich placer diggings on Louse creek, a few miles from Grant's Pass, have found one of the ledges which feed their mine. They sacked eight sacks of ore for shipment the other day, which are valued at several hundred dollars per sack.

Coast Industrial Notes.

—San Diego talks of a new \$1,000,000 hotel.

—A Fairhaven, Wash., man shipped 1000 pounds of smelt by express to Dakota and Montana points last week.

—The committee having charge of the unemployed at Riverside has decided to reduce the pay of married men from \$1.25 to \$1.

—The owner of the United Verde copper mines in Yavapai county, A. T., is to build a railroad to connect with the Santa Fe, a distance of twenty-eight miles.

—Spokane, Wash., is elated over the prospect that the Great Northern Railroad Company will build a large steel bridge over the Spokane river, near that city.

—The Southern Pacific has notified the Santa Fe that it will refuse to interchange passenger business via Los Angeles after February 23. Trouble will probably result.

—A rumor of good authority is around South Riverside, to the effect that the tin mine company will soon put on a small force of men to sink the present shaft deeper.

—Mason county, Wash., cut more than one-third of the logs put into Puget Sound or its tributaries in 1893. The total product of the country was 101,920,770 feet, valued at \$560,564.

—A movement is on foot in Seattle to organize a company to cure fish. Cod and halibut abound in northern waters, and enterprising business men see in this scheme big money.

—Water has been turned into the mains of Vallejo's new water system, which cost \$250,000 and is owned by the town. Everything worked satisfactorily. A big celebration is planned for some day this week.

List of U. S. Patents for Pacific-Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING JAN. 23, 1894.

513,228.—CAR BRAKE—S. V. Bahne, Ellensburg, Wash.

513,300.—GAS-LIGHTER—W. L. Brown, S. F.

513,059.—THRESHING MACHINE—S. D. Crockett, Seattle, Wash.

513,232.—ROTARY ENGINE—Thos. Harding, San Jose, Cal.

513,330.—TRIMMING STEREOTYPE BLOCKS—A. Keyser, Oakland, Cal.

513,124.—BUNK FOR LOGGING TRUCKS—C. D. Matheny, Seattle, Wash.

513,125.—MILE RECEPTACLE—J. M. Mathews, Seattle, Wash.

513,335.—PLOW—F. S. Moore, Hanford, Cal.

513,208.—FRUIT CAR—H. A. Smith, Los Angeles, Cal.

513,216.—CONCENTRATOR BELT—H. J. Summerhayes, S. F.

513,347.—MAGNETO-ELECTRIC MACHINE—H. H. Taylor, Los Angeles, Cal.

513,350.—RHEOSTAT—B. C. Van Emon, S. F.

513,221.—SAUCEPAN—R. B. Vanderburg, Long Beach, Cal.

513,222.—SOLDERING IRON—R. B. Vanderburg, Long Beach, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

APPARATUS FOR TRIMMING STEREOTYPE BLOCKS. Albert Keyser, Oakland, Cal. No. 513,330. Dated Jan. 23, 1894. This invention relates to a device for trimming stereotype blocks. Its object is to hold the block in place so that it can be trimmed into an exactly rectangular form to fit wherever it is to be used. It consists of a frame or stock with longitudinal bed or channel provided with side walls and a holder for the trimming file with guides upon which it travels so that it can be moved back and forth upon the frame and above the block

which is to be trimmed. The height of the movable trimmer is constant and at a point which will trim the block so that it will be exactly type high. The sides and edges are trimmed by fixing the block within the proper holder and turning the file-carrier upon edge. It has a tongue formed upon this edge which travels in a rabbet or groove in the holder, which thus carries it in exact line as it is reciprocated, and the block is thus trimmed off to any required degree and with accuracy.

ELECTRIC GAS-LIGHTER.—W. L. Brown, San Francisco. No. 513,300. Dated Jan. 23, 1894. This invention relates to that class of electric gas-lighters in which electrical contact is made and broken between the electrodes in the vicinity of the gas-burner, whereby the electric spark produced will light the gas. The object of the invention is to provide a simple, effective and easily operated gas-lighting device, which is dependent upon and is simultaneous with the operation of the ordinary gas-cock key, so that no instruction need be given in the manner of lighting the gas. A cam is fixed upon the key which opens the gas passage. When the key is turned off the pin or stud of the electrode arms lies in front of the cam passages at the point of the tongue. When the key is turned to allow the gas to pass, the eccentric or cam moving the pin or stud raises the latter, lifts the arms so as to bring them into electrical contact just before the key reaches its full open position, and this contact is broken by a little further movement of the key so as to produce a spark by the separation of the points.

AUTOMATIC RHEOSTAT.—B. C. Van Emon, San Francisco. No. 513,350. Dated Jan. 23, 1894. This invention relates to rheostats for varying the resistance of electric currents by means of a step-by-step change to either reduce or increase the length of the circuit. It is more especially intended to be used in the armature circuit of a constant potential motor for the purpose of starting and stopping the motor in the proper manner. I employ a rheostat having a switch of a sufficient number of points of contact so that an electrically connected lever will sweep across these points to either withdraw or induce the parts or divisions of the

rheostat according to requirements. In my invention, the lever is automatically operated whenever started by any external means, and it then slowly cuts out the resistance from the circuit or rapidly introduces it, as the case may require, without further external aid. The mechanical and automatic devices are operated in various ways, depending upon the service the motor is performing, such as the operation of a pump by which water is raised from a lower to a higher receiver or forced into a pressure receiver, in which case a cock or valve is opened at the proper time to admit water into a cylinder so as to actuate a piston which is connected with the rheostat lever.

THE GOLD AND SILVER EXTRACTION COMPANY, OF AMERICA.

LIMITED.

MacARTHUR-FORREST CYANIDE PROCESS.

CAPITAL, £110,000 STERLING.

To MINE OWNERS and others having Refractory Gold and Silver Ores hitherto untreatable at a profit, the MacARTHUR-FORREST CYANIDE (Patent) Process of Gold and Silver Extraction offers a solution of the difficulty.

The chief features of this process are

Simplicity, Economy in Working and Small Cost of Plant.

THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS

1891. MORE THAN DOUBLE THIS CAPACITY with one-half less power and occupying less than one-half the space of any other concentrator. Built of Best Steel and Wrought Iron. Strong and Durable. Price \$575 f.o.b. Send for Catalogue and Testimonials. THE IMPROVED MACHINE HAS THE FOLLOWING MERITS: First—The improved belts, which consist of seven, are constructed and arranged so as to allow each belt to receive a portion of the pulp in such a manner as to relieve the machine of its load, thereby giving it twice the capacity of other concentrators, and enabling it to work from 12 to 15 tons of ore per day. Second—The machine equalizes the load by having several compartments, thereby working more regularly and with much less attention than is necessary to give other concentrators using wide belts. Each of the belts on this machine takes care of the pulp that is allotted to it—in this way preventing the pulp from running to the lower side of it, as is the case when a machine becomes out of level where wide belts are used. Third—The belts run on a perfect line, needing no adjustment to prevent their running from side to side, as in other concentrators. Fourth—The belt surfaces are improved by indentations and corrugations, causing the Concentrator to save fine sulphurets and quick-silver, and perform close work. Fifth—The belts have fluted or corrugated edges, to form an expanded top edge, which effectually prevents from cracking. Sixth—The feed arrangement is perfect. Seventh—The machine is constructed of iron, with steel crank-shaft self-oiling boxes, and everything made in the most thorough manner, enabling it to run with very little attention or wear.

Was awarded the Highest (Bronze Medal) Premium at Mechanics' Institute, 1890 and 1891.

Send for Catalogue and Testimonials. THE IMPROVED MACHINE HAS THE FOLLOWING MERITS: First—The improved belts, which consist of seven, are constructed and arranged so as to allow each belt to receive a portion of the pulp in such a manner as to relieve the machine of its load, thereby giving it twice the capacity of other concentrators, and enabling it to work from 12 to 15 tons of ore per day. Second—The machine equalizes the load by having several compartments, thereby working more regularly and with much less attention than is necessary to give other concentrators using wide belts. FULTON ENGINEERING AND SHIP-BUILDING WORKS.

Successors to FULTON IRON WORKS (Hinckley, Spliers & Hayes), and F. A. HUNTINGTON.

OFFICE AND BRANCH WORKS: 213 FIRST STREET. - - - MAIN WORKS: HARBOR VIEW, SAN FRANCISCO, CAL.

MINING AND MILLING MACHINERY.

ADAPTED TO EVERY DESCRIPTION OF MINING AND MILLING.

Manufacturers of the TUSTIN PULVERIZER: Adapted to Wet or Dry Crushing.

Also the well-known HUNTINGTON CENTRIFUGAL ROLLER QUARTZ MILL.

Special Descriptive Circulars of these Mills sent on application.

Specialties Manufactured by us:—"HUNTINGTON" BLAKE ROCK BREAKER; "FULTON" BLAKE ROCK BREAKER; TRUE VANNERS; "BOSS" CONTINUOUS SYSTEM.

Manufacturers of all kinds of ELECTRIC LIGHT AND ELECTRIC R. R. AND CABLE R. R. PLANTS.

STEAM ENGINES—Plain Slide Valve, Corliss High Pressure, Corliss Compound Condensing & Non-Condensing.

Agents and Manufacturers of the De La VERGNE REFRIGERATING MACHINES, FILTERS OF THE NEW YORK FILTER COMPANY.

Sole Agents for THE DEANE STEAM PUMP, ARMINGTON & SIMS ENGINES, LEFFEL WATER WHEELS.

TUSTIN'S PULVERIZER—Works Ore Wet or Dry.

CENTRIFUGAL ROLLER QUARTZ MILL.

Electricity in Montana Copper Mines.

It is announced in Butte that electricity is to be used extensively in connection with the development of the copper properties owned by W. A. Clark. The Rothschild brothers are said to have become interested with Mr. Clark, and to have dispatched to the ground a representative of a large English manufactory of electrical machinery.

It is said that the plans contemplate the purchase of five electric hoists, nine electric pumps, both for station and sinking purposes, and electric drills. In fact, steam power will not be used around the mines for any purpose. A mammoth smelter will be erected near the site of the Butte Reduction Works, and this will also be operated by electric motors, and the electrolytic process of treating the ore will be adopted. To furnish the current for the mines and smelter the company will install its own dynamos to furnish the motive power.

Electric cars will convey the ore from the mines to the smelters, and the handling of the ores by elevators will also be accomplished by the use of electricity.

It is understood that another proposition was discussed by the company, viz: The erection of the smelter at the Big Hole river, but this scheme was abandoned in the belief that better results could be obtained from the use of the electric fluid.

If Congress adopts the recommendation of the House committee, the appropriation for rivers and harbors will aggregate \$8,300,000, against \$14,166,153 in 1893. It is obvious, therefore, that it will be difficult for any particular section to secure a large appropriation, and there is danger that California will be shut off with a very small loaf. Indeed, Congressman Caminetti has already declared against any appropriation for Oakland harbor and Petaluma creek, and there is a very pretty row over his stand, which is of course in the interest of the Sacramento river and tributaries. The delegation from California now

FORDYCE LAKE AND DAM—See page 85.

in Washington may not seem to have accomplished much, but very probably it has been instrumental in saving the item for this State from complete emasculation. The miners' delegation ought to be able to do as much for the restraining dams.

THERE are signs of renewed agitation of the silver question, for some months displaced by the discussion of the tariff. A meeting of prominent citizens has just been

held in Boston to promote the establishment of international bimetalism, and a representative committee was selected to push forward the work. President Andrews of Brown University was elected chairman. The promoters are opposed to the free coinage of silver by this country, but believe that the repeal of the purchasing clause of the Sherman act affords an excellent opportunity for advancing the cause of international bimetalism. They think the needs of commerce will soon compel the international use of silver as well as gold. The committee includes merchants, legislators (national and State), professors, lawyers, railroad presidents and trustees of large concerns. In order to further their objects a series of lectures and public discussions will be arranged, and a great quantity of circulars will be distributed broadcast. Congress seems now to be in the humor for some sort of legislation recognizing silver, and so, perhaps, the outlook is not so gloomy as it appeared a few months since.

RUMORS come from the Cœur d'Alene mines that the labor troubles of 20 months ago are about to be renewed. The Italian miners are the cause of dissension. If reports be true, the edict has gone forth that they must be driven from the Cœur d'Alenes. The former conflict was attended by bloodshed and destruction of life and property. The situation is greatly aggravated by the depression that prevails throughout the Cœur d'Alene region. But while this may be a leading cause in fomenting trouble, it is likely to be also an important factor in ending it, for the very simple reason that the miners' union is not as powerful as it was, and the owners would not look upon a season of idleness with grave consternation; that is to say, their position cannot be rendered much worse by a cessation of operations. It is a fact that a majority of the Cœur d'Alene mines are operating without expectation of present profit and because it is desired to afford its employees means of subsistence. The time to strike is therefore not auspicious.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Fordyce Lake and Dam; Lake Spanling Dam, 81, John Spaulding, Superintendent South Yuba Water Co.; Fordyce Lake, 85. View of the Midwinter Exposition Grounds and the Golden Gate, 87.
 EDITORIALS.—Electricity in Montana Copper Mines; Miscellaneous, 81. Carson River Mining; A New Rotary Mill; The New Tariff Bill; Miscellaneous, 82. Needed Changes in Mining Methods, 83.
 MISCELLANEOUS.—The South Yuba Water Company, 85-86. The California Mining Exhibit; New Method of Treating Ores, 86. Nickel-Steel in the Arts; The Midwinter Fair As It Is, 87. An Address in Favor of Good Roads; History of One Cour d'Alene Mine, 88. Slickens; Foundry Notes, 83. A Big Electric Transmission Scheme; Mines and Mills of Nevada City District; Labor in Grass Valley Mines, 84. Coast Industrial Notes; Patents, 96.
 CORRESPONDENCE.—The Meteor at Candelaria, Nevada; Mountain Mines—Tuolumne County, 84.
 SCIENTIFIC PROGRESS.—Submarine Photography; Variability of the Wind; Explosiveness of Coal Gas; Chromium and Aluminum; Artificial Ice; How to Mend Crockery; To Arrest a Cold, 89.
 MECHANICAL PROGRESS.—Automatic Fog Signaling; Wood-Working Machinery; Steam Engines; Stone Work; First Iron Bridge, 90.
 ELECTRICITY.—Transmission of Power; Operating Lock Gates Electrically; Temperature by Photography; Metal from Pulp; Diamonds in Electric Arc; Singular Origin of Fire; Electricity and Tricycles; To Stop Runaways; Trolley Accidents; In a Gold Cycle, 94.
 USEFUL INFORMATION.—Do Not Cough; Purification of Resin; The Humming-Bird at Home; Historic Battlefields; Powerful Crane, 90.
 MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 93.
 THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 95.

The long-pending transfer of the Idaho mine, in Grass Valley, to its new (Maryland) ownership was consummated last week. S. P. Dorsey will be the general manager and superintendent and Victor Dorsey will be acting superintendent. Mr. Farnham, who has been shift boss at the mine, will be foreman in place of John Carter, and the latter will be the chief timberman. Thomas Dunkley will still be the chief engineer at the mine, and no further changes for the present are anticipated. Eugene C. Creller, who has long been superintendent, retires with a most creditable record as a successful and intelligent executive. It is expected that the new owners will continue vigorously the work of restoring the hoisting works, recently burned, and that the mine and mill will, within reasonable time, again be in active operation. The transfer of this property consummates a most important mining deal. It is the happy conclusion to vexatious and expensive litigation between the two properties; and it is an assurance that the mine which has been the largest producer in the history of California quartz properties will continue to be a leading factor in our gold production.

The following table of admissions to the World's Fair and Midwinter Fair, respectively, for the first ten days after opening makes a good showing for the latter, taking all the circumstances into consideration:

SAN FRANCISCO.		CHICAGO.	
Jan. 27.....	72,248	May 1.....	187,657
Jan. 28.....	12,312	May 2.....	19,544
Jan. 29.....	8,270	May 3.....	28,607
Jan. 30.....	8,092	May 4.....	24,186
Jan. 31.....	5,823	May 5.....	20,861
Feb. 1.....	7,254	May 6.....	28,860
Feb. 2.....	9,253	May 7.....	36,689
Feb. 3.....	14,908	May 8.....	28,455
Feb. 4.....	13,154	May 9.....	32,153
Feb. 5.....	6,629	May 10.....	26,261
Feb. 6.....	6,629	May 11.....	26,261
Total.....	158,879	Total.....	277,138

The Chicago fair cost twenty times as much as the San Francisco show, and was of course larger in every way; but the attendance is not proportionately larger.

DRIFT MINING has never made much progress in Shasta county, but it is known that the county contains several ancient river beds which would pay well for development. One or two enterprises are already on foot. George Martin, O. E. Nash and County Treasurer Jackson are driving a tunnel into a hill near Redding, on the east side of the Sacramento, with confidence that they will find an old channel. The tunnel is now very nearly through rimrock. The late Erastus Parsons, before his death, proved the existence of a pre-historic gravel deposit under the sandstone capping on Oregon gulch by sinking an 80-foot shaft through the sandstone and into gravel that carries gold. Everything indicates that this is an old river channel, and that the gravel carries gold is a settled fact. The Redding Democrat rightly considers the present work a most important enterprise.

Carson River Mining.

It is announced that the Carson River Dredge Company, which appears to be the successor of other organizations which have attempted to work the tailings of the Comstock mines deposited in the Carson river, has at last devised a method by which the material is successfully handled, and it is proposed to go ahead and put in an extensive plant as an adjunct to the clam-shell scoop dredge, and operate on a large scale. The process, in brief, is the utilization of Woodbury concentrators for the extraction of sulphurets, quicksilver and free gold from the tailings, the seven-belt end-shake concentrators appearing to possess peculiar fitness for this sort of work. The tailings are raised from the bottom of the river by means of the scoop, and deposited on a grizzly; the finer material then passes to a revolving screen, where it is prepared for the concentrators. The entire outfit is located on scows anchored in the river.

The recent experiments of the company have been conducted with two concentrators, and it is stated that an average of about \$9 per ton has been realized, at an average expense for handling of about 50 cents per ton. The dredge has a capacity of about 500 tons per day, and each concentrator of about 15 tons per day of 24 hours. It is now proposed to put in 20 concentrators, which will have an aggregate capacity of 300 tons per day. If operations are as successful as are now confidently expected, the profits will be very large, and the plant may be still further increased.

The Carson river has for many years offered an exceedingly inviting field for river mining operations. The various mills along the river have deposited during many years an immense quantity of tailings, aggregating an incredible number of tons. The deposit in places is 25 and more feet deep, and covers the entire bed of the river for many miles. The statement is frequently made that 20 per cent of the entire hulsion output of the Comstock lies in the bottom of the Carson river, but it is probably an exaggeration. It can hardly be expected that more than a small part of the great value of gold, silver and quicksilver known to be there can ever be recovered by any process, no matter how efficient. For many years many methods have been devised for working the tailings, and a great deal of money spent in experimentation. An extensive amalgamation plant was put in by a Philadelphia concern; but, after running some months, a cleanup was made, and little or nothing realized. A project for electric reduction was launched, and many thousand dollars invested, but it likewise proved a disappointment. But the scheme was so attractive, and was so certain to prove very remunerative, if ever the right method was secured, that speculators persisted, and still persist. It is to be hoped that the latest venture will be a success. It certainly promises much.

The Carson River Dredge Company owns 15 miles of the river bed, and therefore has abundant territory for very large operations. It is said to have made an investment of \$100,000 in its mining outfit alone. It has been conducting its concentration experiments for several months, with uniform success, so it is stated. The material recovered is mostly concentrates—about four-fifths—and one fifth free gold, besides a quantity of quicksilver.

SILVER has been steadily declining during the past ten days, the London quotation of this day (Thursday) being the lowest on record in that market—29½d. The New York quotation is not at this writing at hand; but yesterday it was 64½c, or only 2½c above the bed-rock quotation of June, 1893. The causes, of course, for the decline are the excess of supply over demand. The United States is not likely to become a purchaser for coinage purposes for some time, and the use of silver in this country is practically limited to the arts. It is, of course, impossible to say how long this deplorable condition of things will last.

THE silver question has again presented itself to the House. Bland, chairman of the House Committee on Coinage, has made a favorable report on the bill to coin the silver seigniorage in the treasury. At the same time, Stone of Pennsylvania presented an adverse report from the minority of the committee. The Bland proposition is advanced with a view of supplying the treasury with \$56,000,000 in silver certificates to meet current expenses. It was originally intended that the coinage of this amount of silver seigniorage would prevent Carlisle issuing bonds. It is probable that the bill will pass.

THE Debris Commission held a meeting Tuesday afternoon in the Flood building. Licenses to work mines were granted to Nathan Gardiner, proprietor of the Red Hill mine at Ono, Shasta county, and to the Fifty-four Flat Mining Company of Amador county.

A New Rotary Mill.

Mr. William A. Merralls, M. E., of this city, has received a patent on an ore-crushing mill which presents some features that are a variation of and are claimed to be an improvement on stamp and other mills. The essential principle is the Chilian type of mill. The invention, as described, consists of certain novel features of construction, a novel combination and sub-combination and arrangement of parts, rotary wheels, hinged boxes for the shaft of the wheels to run in, a cylinder within the pan or chamber, and provided with a piston working up and down in the cylinder and operated by either water, air or steam; halls, collar bearing, bearing halls running in a lubricant; a spider, suitable springs, pipe connections to a cylinder, relief valve, a pump and pressure tank for holding water or air under pressure. Conspicuous features of the invention are an attachment of the air, steam and water cylinder, so arranged as to exert a direct pressure of 25 tons upon the rollers; an arrangement of screens to prevent slimes; and an easy device for the elevation of the rollers when any obstruction occurs in the pans, or when temporary repairs are necessary, or for any other purpose, without unloading the mill; and such solid and compact construction that undue jarring and straining are avoided.

Mr. Merralls furnishes the PRESS with the following statement of his claims of the new mill's points of superiority over stamp mills:

1. The mill makes very little, if any, slimes.
2. The mill is a better gold amalgamator and will save from 10 to 50 per cent more gold in the ore than is possible with stamps.
3. The amalgamation in the Merralls mill is done in the inside around the cone, out of the way of the crushing rolls, consequently there is very little, if any, flouring of the quicksilver.
4. The wear and tear of the Merralls mill is not over 4 or 5 cents per ton.
5. There are no expensive foundations to be put in, and if it should be desired to move the mill at any time, it can be done at a small expense.
6. The power will only be about two-thirds of the power required to drive a 10-stamp mill.
7. A six-foot mill will crush as much ore as 15 stamps will do, with same size mesh screen.
8. The ore as crushed will concentrate much better than the pulp from a stamp-mill, because the pulp is more uniform and granular.
9. No oil can get into the circular chamber to interfere with amalgamation.
10. The dies and rings wear smooth and even, and not in holes or flat surfaces.
11. The power can be put on or off the crushing wheels instantly.

Mr. Merralls is making arrangements to manufacture his mills in San Francisco.

The New Tariff Bill.

The Wilson tariff bill, as it passed the House, contained several features most odious to the mining interests of the West. These have already been pointed out in the PRESS. It now seems likely that the bill will pass the Senate and become a law, notwithstanding the fact that the judgment of the country, as indicated in recent elections, is most clearly against it. The measure is weighted down with an income-tax provision, and there is some talk of an effort to further load it with a free-silver amendment, in hope of alienating enough friends to defeat the final passage. It is doubtful if this latter proposition will succeed, however desirable free silver may be, and however earnest and aggressive are its friends. The vote on the bill in the House was pretty closely on party lines. Tremendous pressure will be brought to bear on the Senate, so that, if no emergency arises, it may reasonably be expected that similar conditions will prevail and similar action be taken there.

Still, the victory of the tariff-reformers is by no means won. The bill will not be law until it has passed the Senate and is signed by the President. There is ample opportunity yet for the setting of legislative traps into which the bill may fall. It cannot be doubted that the opponents of the measure will exhaust every parliamentary device to secure its defeat. A protracted struggle is to be looked for.

THE official report of the production and coinage of gold and silver in Mexico during the fiscal year 1893 is out. It shows the production of \$1,400,000 gold and \$48,500,000 silver. In the face of the depreciation of silver, this is the largest year's production in both metals Mexico has known in many years. The mintage for the year was \$361,672 gold and \$27,160,876 silver. The low amount of gold coined arises from the fact that the monetary system of Mexico is now operated practically on a silver basis.

Needed Changes in Mining Methods.

By W. S. Chapman.

An entire change in the management of mines is essential to the development of the great interest of mining in California. It has been the almost invariable custom to build a mill before one had a mine. The whole country is dotted with useless mills where no mines exist. When the writer came to the State of Nevada, in 1864, he found quartz mills, having cost from \$50,000 to \$250,000, all over the State, and the rule was that there were no mines. In Amador county, in this State, it is safe to say that only four mines have been systematically opened and developed. The first thing to do is to sink a shaft, deep enough to prospect the mine thoroughly, so as to know whether you really have a mine or not. The shaft should be sunk, ordinarily, to 1000 or 1500 feet, levels opened at each 100-foot station, the veins crosscut at each level, and when that work has been done, the miner will know whether he wants a 20-stamp mill, a 40-stamp mill, or a 100-stamp mill, or any mill at all.

Four mines only have been systematically opened in Amador county, where there are more than 100 now known to exist that have never been opened; but attempts at prospecting have been made upon all of them. The four mines I speak of are the Hayward mine at Plymouth, the Zeily and Kennedy at Jackson, and the Keystone at Amador. In every one of these instances the mines have been partially worked and abandoned, but when taken hold of by capital and developed in a business-like way, they have all paid very largely. The Zeily is a very low-grade proposition, running only about \$3 to \$3.50 per ton, sulphurets and all, but by the systematic management of Mr. Dutard, it has been judiciously developed and has paid dividends every year. But for the sulphurets which he carefully saves, his mine would not pay more than running expenses.

In Tuolumne county I know of a large and very valuable mine which only pays 50 cents a ton in free gold, but by the careful saving of the sulphurets and "slums" it pays regularly from \$20 to \$22 per ton. This mine, after running the pulp over the concentrators, then onto large canvas floors and then into a system of settling tanks, thus saves the sulphurets to almost the smallest percentage. In this way the mine, although abandoned by various companies years ago, has proved to be a very good paying property and is very extensive and valuable.

Even the Comstock, when I came to Nevada in 1864, allowed the "slums" to run down the ravines and gulches into Carson river. That river has carried millions of tons to the sink of the Carson. Now these tailings have been found so valuable, after passing so far through the gulches and ravines, that mills have been erected at the sink to work them over again. By the present manipulation of the same class of ores, after the experience that those men have had, and after years of study and attention to the business, those tailings are not allowed to escape until nearly all their value has been extracted. It is estimated that in the working of the Comstock from 20 to 40 per cent of the value of the ores of early times went down the gulches into the Carson river. The difference we now find is the result of thirty years of constant experience, study and attention.

The same rule would apply to the gold mines of California. In the early days such a thing as concentrators were unknown. No sulphurets were saved at all. Even the great Idaho mine at Grass Valley in this State, from which has been extracted \$13,000,000 gold, was worked many years without even having a concentrator of any kind. Now it is found that millions of dollars were run down the gulches with the tailings, which with present appliances and present experience could have been saved, over and above what was realized.

Mines must be more economically worked than they have been. There is no reason why wages should remain as high as they are. While I am not in favor of reducing workingmen's wages as a rule, yet I think it would be far better for the unemployed to work in the mines for \$2 a day than to be seeking work in the park or around the city, or any place where they may procure work at a dollar a day, and most of the time having nothing to do at all.

In the copper mines near Lake Superior, where all our miners might receive many very valuable lessons, mines are worked to great profit where if in California they would not pay the board of the miners. Now, why is this? California has a better climate, both in summer and winter, and is the *cheapest place in the world to live*. Nearly all the gold mines of California are situated in the pleasantest climate in the world, where fruits and garden stuff can be raised almost for the planting, where schools and all the advantages of civilization can be had, and yet men will work on a farm through the heat of summer and the inclemency of the winter for \$20 to \$25 per month, and

the same men going into a mine, where it is dry in winter and cool and pleasant in the summer, must have from \$2.50 to \$3 per day, or else they will go to the city and beg for an occasional day's work to get money to sustain life.

In one of the important copper mines near Lake Superior, from which they are now hoisting ore from 1700 feet below the surface, shipping it three and a half miles to the furnace, the ore is very hard and difficult to crush, and pays but three-fourths of one per cent in copper. The copper is worth eight cents per pound, and when saved by the most careful manipulation is worth only \$1.20 per ton, and yet that mine has paid hundreds of thousands of dollars in dividends. The development of the Oripple Creek mines of Colorado and the recent purchase by Senator Jones and Mr. Haggin of a very extensive mine in another part of Colorado shows that all over the country those demonetized silver miners are prospecting for gold, and many of them with great success. All those miners, instead of going to the cities, where work is never abundant and where wages are always low, would better have gone to the gulches, with pick, pan and shovel. There is scarcely a gulch in the Sierras that would not pay more than the unemployed in San Francisco get at the park.

Mining Is Not a Gamble.—Mining has heretofore been called gambling. I denounce the expression as inapplicable to any such legitimate business as mining. It is unfortunate that when the miner, without money, goes into the mountains, camps out and lives in a rough manner, finds his mine, and, when he has developed it sufficiently to know that he has a mine, and wants machinery and a mill, and goes to the city, the capitalist—who ought to stand in with him and help him to develop the mine—will not assist him in any way, as a rule. But the time has come when this sort of thing should and will change. It is now apparent that no business in this State, or in any of the gold-producing States, is considered so safe or so profitable as mining. And the time will come very soon when mining will not be called gambling, but when the miner will have as good credit as the fruit-grower, the wheat-producer, the cattle-raiser or men engaged in any of the other ordinary occupations of life. The gold product of California for 1894 will be about \$20,000,000. Shut down all the mines, and take off that supply of gold, and then indeed we can talk about "hard times;" but as long as we produce that amount of money—and that amount increasing annually—we will never see hard times, such as the Middle, Northern and I may say Eastern States now suffer. There can be no reason why California cannot work mines a little cheaper than Michigan or any of the Eastern States. Coal mining in Pennsylvania does not cost 40 per cent of our present cost of mining in this country, and yet all supplies needed by the miner can be bought as cheap, and many of them very much cheaper here than in Pennsylvania, Illinois or any of the coal-mining States.

People generally have very little knowledge of the mines of California. Many old Californians think that gold mining is about finished in California; that there is very little gold left in the mountains, when in fact the mountains have not been prospected. And when we look over the single county of Amador, through which the mother lode passes almost without a break, and find that but four mines in that county have been developed to any considerable extent, it is not difficult to see that the scarcity of mines is due to the want of vigor and enterprise to develop them.

W. S. CHAPMAN.

Slitkens.

THE Puget Sound Reduction Co. has completed their plant at Everett, Washington.

SPOKANE is making an effort to secure the next meeting of the Trans-Mississippi Congress.

ANOTHER expedition is being fitted out at Vancouver, B. C., to search for supposed hidden treasure in Cocos island.

THE Alta Gold Mining Company has incorporated; directors, W. M. Hall, W. S. Miller, F. S. Chadbourne, J. P. Edhoff and J. E. Doolittle.

A STAMP MILL was completed in Kennedy district, Humboldt county, Nevada, last week, and the event was celebrated with fitting ceremonies.

THE directors of the Morning Star mine, situated at Iowa Hill, have declared a dividend of \$4 per share. The mine is in a splendid condition.

MINING assessments falling delinquent in February amount to \$150,300, of which Nevada mines want \$131,300 and California mines \$19,000.

COLONEL W. J. SUTHERLAND of the Candelaria companies has given up his proposed trip to Central Africa, and will again visit this coast next March.

J. V. KAELEY of Pioche, Nev., who has been in New York for some time past, is reported to have sold the Clementina gold claim in Yellow Pine district.

THE Granite mine at Wallace, Idaho, one of the largest producing mines in the Comstock district, has shut down, it is said for good. All the men have been paid off.

THE Comstock payroll for the month of January was \$65,214.25, an advance over the previous month of \$4370. As a

number of new explorations will be undertaken this month, the Virginia Chronicle says that the February payrolls will probably show a further increase.

MAARTIN MYERS, a prominent mining man of the Kaslo-Slocan district, is in the city, for the two-fold purpose of attending the Midwinter Fair and investigating the cyanide process.

A CRUSHING of ore from the Osborn Hill mine, Grass Valley, has just been finished at the Rodgers mill in Boston Ravine. The ore averaged about \$30 per ton, not counting the sulphurets.

THOMPSON CAMPBELL of Butte has five sapphires said to have been taken from the gizzard of a Montana turkey. The sapphires are all of good size and one of them weighs about two karats.

"JIM" WADSWORTH, who recently went to South Africa from the Comstock district with fond hopes of recouping his fortunes, is reported to be on his way back, after only a few weeks' stay in Johannesburg.

THE Mercur mine, in Mercur district, Utah, is said to have developed a vein of gold-bearing quartz 14 feet in width showing an average value of from \$8 to \$16 a ton. The mine has been sold to Denver capitalists.

W. B. BUCKMINSTER, representing the California quicksilver mines, is in Washington again and will endeavor to secure a hearing before the Senate finance committee in his attempt to secure the restoration of the duty on quicksilver.

It is claimed that no other town can duplicate the mineral exhibit sent from Lovelock to the Midwinter Fair. It will include the following minerals found near the town: Iron, lead, copper, bismuth, antimony, nickel, cobalt, borax, silver and gold.

THE bill of Senator Dubois of Idaho to give several Western States one-fourth of the money received from them by the Government for mineral lands, to support schools of mines, has been adversely reported by the House Committee on Public Lands.

TAYLOR D. McLEOD, the well-known mining man, has returned to the city from Seattle. His address in San Francisco for some time will be 1007 California street. Mr. McLeod will shortly leave for Arizona, where he has important mining interests.

THE Grass Valley Union has just issued a very creditable Midwinter Fair edition. It contains complete and accurate reviews of the mining and various other resources of Nevada county. Typographically, the number is well arranged and very tasteful.

SUPERINTENDENT HOFER of the United States Mint at Carson has received instructions from Washington to dispense with H. J. Humphreys, weigh clerk; W. R. Raddall, bookkeeper; Ernest Christian, melter; G. A. Spencer, helper; and A. S. George, yardman.

A LARGE portion of the male population of this section are interested in mining in some manner, and many of the rest are following suit, says the Jacksonville Times. Southern Oregon is destined to become one of the great mineral-producing sections of the United States.

THE Silver Convention which was to have been held at Des Moines, Iowa, February 22d and 23d, has been postponed to March 21st and 22d, on account of the first date selected conflicting with a meeting of the Pan-American Bimetallic League at San Francisco and other meetings previously arranged.

MISS EMMA BLACKBURN of Red Bluff is said to be the best female mineralogist in the State. Her life has been spent among mining people and she has picked up a knowledge of minerals possessed by few of her age and sex. She is said also to possess one of the finest cabinets of minerals on the coast.

A SICH STRIKE is reported from the Gold Rock mine, 20 miles from Yuma. From the first the ore has yielded well in free gold. Last week, at the depth of 150 feet, the miners struck a chamber of ore running into the thousands per ton. During the week the body has opened wider and richer. It is considered to be the richest strike ever made in that section.

THE second clean-up at the new cyanide mill at Deadwood shows even better results than the first run, says the Deadwood Times. The following details are given by Secretary Taylor: 42½ tons of ore from the company's property on Black Tail gulch, assaying \$20 per ton, and 11 tons and 800 pounds from the Ajax group on Squaw creek, assay value \$32.35 per ton, were treated. The result was a gold brick weighing 66 ounces, worth \$1168.20, showing an extraction of 91.33 per cent, with a loss of but 1½ pounds of cyanide per ton. The brick contains both the gold and the silver contained in the ore, the former being 907 fine.

COLONEL THOMAS confirms the statement that he has resigned the position of superintendent of the Comstock Tunnel Company. His resignation was forwarded to the directors on January 23rd, to take effect on April 1st. The Colonel has had charge of the Suto tunnel for 14 years. As soon as it became known that he had sent in his resignation the superintendents of Comstock mines and the principal members of the boards of directors telegraphed to New York to the Comstock tunnel directors to refuse to accept the resignation. Included in those who desire the Colonel to continue in the position of superintendent are John W. Mackay and ex-Senator Fair.

Foundry Notes.

FOUR Woodbury concentrators have just been sold in Colorado.

THE Mountain Lion mine in Josephine county, Oregon, has just bought a five-stamp mill and a Woodbury concentrator.

A McGLEW concentrator has just been sent up to the Alentian islands for operation in a mine owned by Louis Sloss, Jr., and others of this city.

THE Salem, Or., Water Company has just filed an order with the Dow Pump Works for the building of a Dow improved vertical triplex pump, to be ready for shipment in 90 days. This new piece of pumping machinery will have a 30-inch stroke and will be 16 inches in diameter. It will have a capacity of 5,000,000 gallons per 24 hours.

Improvement in Concentrator Belts.

One defect in concentrator belts is the liability of the flanges to crack. No matter what the shape of the flange is, there is always a tendency at cracking where there is an edge. With this idea in view, Mr. H. J. Summerhayes has patented a flange without an edge. As will be seen by

the accompanying cuts this flange is hollow, straight on the inside and curved on the outside. The advantages thus gained are: First—As it has no edge, the liability to crack is reduced to a minimum. Second—There is a straight wall on the inside, thus allowing the proper use of water and the keeping of the sand corner under control. Third—Having the most of its weight on the outside, the flange is drawn outward as it passes over the end rolls, thus further diminishing the strain and lessening the possibility of cracking.

A Big Electric Transmission Scheme.

The Clear Lake Electric Company has been organized for the purpose of carrying out one of the largest electrical projects yet announced on the Pacific Coast, or, for that matter, in the United States. For boldness it nearly rivals the scheme to utilize the power of the Niagara falls to transmit electric power for many mills. In short, the company proposes to transmit electrical power from a point on Cache creek, Yolo county, 72 miles to San Francisco.

The amount of capital stock is set at \$5,000,000, and the names of the incorporators are: James Armstrong, president of the Sonora Electric Light Company and vice-president and general manager of the Pacific Electric Storage Company; James H. Culver, secretary of the Mechanics' Institute; Francis X. Simon, manager for Britton & Rey; J. B. Treadwell, the capitalist, and Cameron H. King, the attorney.

The general objects of the corporation are to acquire interests in land and water rights in the counties of Yolo and Lake; to construct dams, reservoirs, canals and other appurtenances for the purpose of using the water acquired by these rights, to supply water for domestic purposes in those counties, and to manufacture and distribute electrical power in various cities, principally San Francisco.

The projector of the company, Ferdinand Formhals, has been for some time engaged in a study of the possibilities of using the overflow from Clear lake, now flowing through Cache creek, for the purpose of operating a plant capable of generating sufficient electricity to supply mills and factories in this city, with the equivalent of 25,000-horse power daily.

The present estimated cost of horse-power in this city, based on the cost of the best Welsh anthracite coal at \$7.50 a ton, almost twice what it costs in the Eastern States, is said to be \$7 a horse-power. About 55,000-horse power are developed daily in this city. A point is made that electric-power can be supplied at less than one-half that of steam-power, besides economy in its use. By the use of separate motors in a factory running many machines, as many or as few can be run as the demands of business may require.

It is proposed to divert the waters of Cache creek at a point near the town of Rumsey in Yolo county, near the end of the Clear Lake and Yaca Valley railroad. From there the power would be conveyed by cables to San Fran-

cisco, a distance in an air line of 72 miles. This plan has been tried in many places. The Drebrum plant, which supplies power between Lauffen and Frankfurt, Germany, it is said, carries the current 108.6 miles.

It is estimated that the cost of supplying 25,000-horse power daily, together with the cost of the necessary land for buildings, the buildings, dams and cable line will be \$750,000. Careful computations have been made of the amount of water daily flowing through Cache creek, with the result that it is estimated that power enough is every day wasted to develop four times as much power as the company proposes to supply.

Another project which will be operated in connection with the establishment of the station at Rumsey is the construction of an electric railroad to Lakeport. The valley of Cache creek affords the only feasible route, but the culverts and bridges required for a steam railroad would be too expensive to make the route profitable. With lighter motive power and lighter cars the road could be constructed at much less cost and be less expensive in operation. With the station established, electricity could be used in the grading operations, still further reducing the cost.

The people of Lake county have offered a bonus of \$50,000 to the first company that builds a road into that county, and the Clear Lake Electric Company will make every effort to secure that bonus.

Mountain Mines---Tuolumne County.

TO THE EDITOR: I send you a description of a few mines situated about three miles from Soulsbyville, Tuolumne county. Some of them are free properties, and can be opened with small capital. They are in the hands of poor men, and they have no money to open them.

First is the Snmmlt mine, which is idle and is a valuable property; two shafts have been sunk on the vein, one to the depth of 80 feet, and there is one ore chute of ore 200 feet in length which has yielded from \$30 to \$100 per ton free gold. The vein averaged about two feet in width. At the water level a good percentage of sulphurets come in, which are of a very high grade. There are other chutes which go from \$10 to \$30 per ton free gold. It is in slate formation, and can be made to pay a good dividend. It is an easy mine to work. A portion of it can be opened by tunnels. There is timber on and near the mine, and good water power, with a fall vertically of about 200 feet with about 600 feet of pipe.

The Champion, near the above mine, is a small vein, but improves in going down. Mill tests give \$16.50 per ton free gold. Water power can be had for this mine.

The Prudhomme mine is also a good property. The vein is in granite formation. Considerable gold has been taken out of this mine. There have been three chutes opened. The first chute is about 90 feet in length and 12 to 15 inches wide; the second is about 60 feet in length and runs up to two feet in width; the third is 30 feet, widening out going down, and is from 1 to 2 feet in width. A portion of ore has been worked down about 75 feet from surface, ore paying from \$16 to \$22 per ton free gold; assay value of sulphurets, \$250 per ton. The Tuolumne Water Co.'s ditch runs by the mine, and there is plenty of timber near the property. It is held by U. S. patent.

The Cordava, owned by the same party as the Prudhomme, is worked from a tunnel. The ore pays well and the vein is of good size. The Tuolumne Water Co.'s ditch also runs by this mine, and it can be prospected with small capital.

MINER.

The Meteor at Candelaria, Nevada.

TO THE EDITOR:—I send a description of the meteor that fell at this place on the night of February 1st. The thermometer registered 15 degrees above zero. At 10 o'clock 7 minutes a brilliant meteor appeared, coming from the southwest. It made a tremendous illumination, suddenly, as if a great flash light was thrown in well-lighted rooms, wherever a corner of window curtain or shade was not tightly drawn. So intense was it in brilliancy that those who were out of doors were dazed, and but few could tell whence it came or whither it went. It was of a dazzling electric blue, like many arc lights had suddenly shot into existence. The illumination lasted about four seconds, disappearing in the northeast. The illumination brought all who were awake to their doors, awe stricken, thinking some slumbering crater had burst into flame.

Thirty seconds later a terrific explosion occurred, like tons of dynamite suddenly exploded, shaking the hills and echoing through the rocky caverns.

It was like a huge bombshell had been hurled in our midst. There followed a boiling and sizzling roar, like an immense mass of red hot iron cooling in water. The sound grew fainter and gradually died away. This lasted about fifteen seconds.

Those who were sleeping and did not see the illumina-

tion were aroused and rushed out of doors, supposing it to be an earthquake or that the crack of doom had come.

When the snow melts and the focus of the explosion is definitely located, a search will be made for the meteorite.

None who saw or heard this meteor will forget it, and they will relate it in future years as a great event; nor will any one here desire to be nearer to those celestial bombs than he was this night. Some ducked their heads to let it go by and considered it a very close shot for a star.

Candelaria, Nev., Feb. 4, 1894. FRED CORKELL.

Mines and Mills of Nevada City District.

From the Midwinter Fair Edition of the Grass Valley Union.

Following is a list of mines, mills and chlorination works of Nevada City district, with stamps and number of men employed:

	Men. Employed.	No. Stamps.
Bellefontaine, quartz.....	8	..
California, quartz.....	6	..
Canada Hill Con., quartz.....	6	..
Cement Hill, gravel.....	4	5
Champion, quartz.....	100	30
Federal Loan, quartz.....	22	10
Floyd & Co., quartz.....	4	..
Gold Flat, quartz.....	15	..
Harmony, gravel.....	40	10
Holmes, quartz.....	4	..
Home, quartz.....	8	..
Knickerbocker, gravel.....	4	..
Manzanita, gravel.....	10	..
Mayflower, quartz.....	5	..
Merrifield, quartz.....	10	..
Mountaineer, quartz.....	45	..
Nevada City, quartz.....	42	20
North Banner, quartz.....	10	10
Odin, gravel.....	15	..
Pittsburg, quartz.....	15	10
Providence, quartz.....	70	40
Reward, quartz.....	10	..
Spanish, quartz.....	35	15
Utah Con., quartz.....	8	..
West Harmony, gravel.....	40	15
Wyoming, quartz.....	10	10
Yosemite, gravel.....	6	..
Totals.....	552	175

In addition to the foregoing, there are many claims where one, two or three men are engaged in prospecting or taking out ore, and of these no account is taken.

IDLE MINES.

Mines with machinery that are now idle, but upon which arrangements are being made to resume work, are as follows:

Banner.....	quartz
Contact.....	quartz
Deadwood.....	quartz
Fountain Head.....	gravel
Montana.....	quartz
Murchie.....	quartz
Nevada County.....	quartz
Sneath & Clay.....	quartz
Texas.....	quartz

CUSTOM MILLS.

	No. stamps.
Locklin.....	5
Nevada County.....	5
Total.....	10

CHLORINATION REDUCTION WORKS.

	Tons capacity per day.
Champion.....	4
Pioneer.....	4
Providence.....	5
Total.....	13

Labor in Grass Valley Mines.

From the Midwinter Fair Number of the Grass Valley Union.

Investigation shows the number of men employed to be as follows:

*Maryland.....	175
North Star.....	175
Empire.....	160
Omaha.....	130
W. Y. O. D.....	70
Osborne Hill.....	33
Orleans.....	32
Electric.....	14
Granite Hill.....	18
Slate Ledge.....	16
Central North Star.....	15
Brunswick.....	15
Hudson Bay.....	12
Centennial.....	10
Pennsylvania.....	10
Wisconsin.....	8
St. John.....	8
South Idaho.....	6
Small mines, about.....	150
Total.....	1057

*Now idle on account of burning of hoisting works.

The wages paid to each man employed will average at least \$2.50 per day. This is a conservative estimate, for nearly all the miners in the district receive \$3 per day, and "top" hands \$3.50 to \$5 per day. From this statement the following deductions may be drawn: Ten hundred and fifty-seven men employed at \$2.50 per day means that \$2642.50 go into the homes of miners in this district every day. Allowing 26 working days a month the amount would foot up nearly \$70,000. For the year the sum would aggregate nearly \$840,000.

In Grass Valley district there are about 250 stamps working in the mills.

The South Yuba Water Company.

The indispensable factor in the development of the great hydraulic mining interest of California, in years gone by, was the presence of a cheap, abundant and regular supply of water, and the necessity is scarcely less imperative in the operation of quartz mines. The enormous dimensions which hydraulic mining at one time assured were possible only because vast supplies of water were carried to the scene of operations by ditches, flumes and tunnels, often elaborate and expensive, and constructed with the highest degree of engineering skill. To insure a continuous flow, winter and summer, natural lakes high in the mountains were turned into great reservoirs by the construction of dams, often at large expense, and the water which accumulated during the winter and spring was thus stored for use during the summer and fall. The companies which undertook to perform this service for the hydraulic and quartz mines played a most important part in the development of the mining industry of California. Their investments were enormous and their incomes generally commensurate with the hazard and dimensions of their ventures. When hydraulic mining ceased, they were all terribly crippled; some became bankrupt, and few have fully recovered from the blow.

In Nevada county particularly the water companies reached the highest degree of usefulness. They became rich and powerful corporations. They furnished all the hydraulic mines and nine-tenths of the quartz mines with water. Since the former have practically ceased their operations, almost the only company conducting a general business in Nevada and Placer counties is the South Yuba Water Company. It bears such an intimate relation to mining operations in these counties that no review of the history of the industry is complete without mention of its achievements.

The South Yuba Water Company is at once a growth and a consolidation, being largely an absorption of less successful and less fortunate rivals. To the original property of the South Yuba Company have been added the property of the Nevada Hydraulic Mining Company (1880), the Bear River Canal Company (1890), the Fall Creek Water Company (1891), and the lakes of the Omega Company (1893). For forty-four years the business of the company has grown from an unpretentious beginning to a corporation having practical control of the watershed and profitable outlets of the entire region. It is almost the sole source of power supply for all the quartz mines of Nevada and Placer counties, the only exceptions being the new mines and mills operated by steam. It furnishes irrigating water for the important Newcastle fruit district. The municipal supply of Nevada City, Grass Valley, Colfax, Auburn, Newcastle, Penryn, Loomis and Lincoln come from the South Yuba. The electric light plants and other public and private works secure their power from the same source. It is within the possibilities that this company will some day provide water for Sacramento and even San Francisco. In Auburn and Newcastle the waterworks are owned by the company outright; in Lincoln there is only a half-interest; in Nevada City and Grass Valley local corporations own and run the system, purchasing of the South Yuba Company. The storage supply of the company is vast. The reservoirs are simply natural basins in the mountains, shut in by costly dams and so converted into lakes. These storage reservoirs are 18 in number and of great size and capacity. The company's watershed has an area of 170 square miles, and lies about the sources of the South Yuba, just beneath the crest of the Sierra Nevadas, in a very wild and almost

inaccessible region. The annual rainfall averages upward of 65 inches. Snow usually comes down in the months of November, December, January, February and March, and at the close of the stormy season it lies from 10 to 20 feet deep on a level. August is far advanced when it is all melted. The entire available water supply of the watershed is probably not less than 200,000,000,000 gallons and

JOHN SPAULDING, SUPERINTENDENT SOUTH YUBA WATER CO.

is ample for all future needs of the company, on the most ambitious estimates. The vastness of the entire storage system will appear from the following table of area, capacity and cost:

FORDYCE LAKE.

Name of Reservoir.	Elevation.	Area in Acres.	Capacity in Gallons.	Cost of Dam.
Meadow.....	7,515 Feet.	300	1,275,000,000	\$ 75,000
Stirling.....	7,200 "	100	340,000,000	20,000
White Rock.....	7,000 "	80	255,000,000	5,000
Peak Lakes, Three.....	6,900 "	150	1,275,000,000	*
Fordyce.....	6,500 "	474	5,950,000,000	300,000
Lost River.....	7,000 "	*	85,000,000	*
Fall Creek Lakes, Six.....	7,000 "	171	1,020,000,000	*
Spaulding.....	4,846 "	215	2,125,000,000	50,000
Omega Lakes, Three.....	5,000 "	85,000,000	15,000

* Records lost.

The entire capacity of all these 18 storage basins is thus 12,410,000,000 gallons.

At the center of the system lies the most important of all—Fordyce, an expanse of 474 acres. It is situated on the north fork of the South Yuba, 16 miles above the head of the Main canal and 7 miles from Cisco, a station of the Central Pacific railroad, and 6500 feet above the sea. The dam, built in 1873 in a gorge at the outlet of the Fordyce valley, was subsequently enlarged and perfected; it is 815 feet long, 72 feet high on the inside and 90 feet on the outside, and in breadth 125 feet at the base. It is constructed of dry rock wall, lined on the inside with three-inch plank; it has a waste weir 100 feet long and 5 feet deep.

The Lake Spaulding dam, on the head of the Main canal, South Yuba river, is a dry rock dam, faced with plank. The dam is 290 feet long, 67 feet high and 67 feet deep, and the outlet is through a solid point of rock, with two waste weirs each 120 feet long. The area is 215 acres and the capacity over 2,000,000,000 gallons. Lake Spaulding forms a collecting and distributing basin for the entire watershed, and through it flow all the waters of the upper storage reservoirs. It serves to check the admission of snow into the Main canal in winter, and also to regulate the amount of supply for the canal system.

Large as the company's storage at present is, it quite fails to husband the entire supply of the watershed. It is calculated that in an average season Meadow could be filled twice, Stirling five times, Fordyce four times, and so on. During a very stormy year, Fordyce could be filled twelve times. The extreme limit of the supply through present outlets is not less than 150 billions of gallons, or twelve times the present storage. The average supply is fully four times the present storage.

Hence the purchase of reservoir sites to meet prospective demand upon the company's resources—500 acres in Summit valley on the very crest of the Sierra, where an escape gorge offers site for a large and effective dam, 160 acres near Tamarack station on the C. P., at the outlet of a deep, broad, natural basin, and 1000 acres of Bear valley, four miles below Lake Spaulding and at the head of Bear river.

The distributing canals form a network over Nevada and Placer counties and measure nearly 400 miles of distance. The dividing lines are carried along the crests of ridges and are thus available for use for power, for irrigation or for municipal supply, out of reach of local contamination and always exposed to aeration by the mountain breezes. The water that traverses them moves down swiftly, often in rushing waves and not seldom in foam, never for a moment stagnant, and is (excepting that taken from Bear river) soft, clear and cold.

The Main canal heads on a narrow rocky gorge, three quarters of a mile west of Lake Spaulding, and receives its supply through a small tunnel, into which the water is diverted by a log dam. From the tunnel an immense wooden flume, of 136 million gallons daily capacity, is carried along the gorge against the face of a perpendicular cliff, on a rocky shelf blasted out for the purpose. Thence onward for six miles, hugging the wall of the ravine and the wooded slope of Bear valley, the flume conveys its chafing torrent, to empty into a

deep, broad canal, which latter passes through a tunnel, and finally pierces a mountain. The Main canal penetrates a mile of tunneling in all, and it is said to have cost the adventurous miners who built it \$600,000.

Where water is required for municipal supply for power, reservoirs, to provide against possible break in the canal lines, are suitably located. These are small and not in any wise elaborate, but in the aggregate they represent a con-

siderable investment of capital. There are twelve such reservoirs for distribution, as follows:

Name.	Elevation, feet.	Capacity in gallons.
Alta.....	3,800	8,500,000
Chalk Bluff.....	3,700	3,400,000
Leonard.....	3,000	13,600,000
Alta Hill.....	2,700	2,550,000
Manzanilla.....	2,850	3,400,000
Blue Tent.....	3,075	34,000,000
Ridge.....	3,500	1,700,000
Auburn.....	1,500	570,000
Loomis.....	400	8,500,000
Loomis (second).....	440	340,000
Camp Far West.....	1,000	2,550,000

In addition to these, the company owns lands covering its rights of way, to protect water rights, for reservoir sites, to prevent hurtful competition, in dimensions 4550 acres; and a number of placer mining claims, in aggregate area 948.27 acres, making a total acreage of 5498.27.

The standard of measurement is the "miner's inch," roughly estimated at 17,000 gallons per diem.

The rate for purposes of irrigation is \$45 a year per miner's inch. As one inch will suffice for seven acres of land, the expense to the farmer is less than \$7 for each acre. This compares very favorably with the rates of other water companies in California and the cost of irrigation in foreign countries.

Water for power is sold in miner's inches, except in case of special contract to deliver it in horse power, and is returned after use to the company's canals; the rate is 18 cents a day. An inch used on the latest designs of wheels will develop one-horse power under 412 feet pressure. Where the fall is considerable, therefore, canal water power is far more economical than steam, which in Placer and Nevada counties costs upward of 60 cents a day. The charge for water sold in bulk to municipalities is 18 cents per square inch and upward, according to amount, cost of delivery, etc.

Where water works are owned by the company, the dues are collected from families on a gross charge for general family use under liberal regulation charges; these average \$2 per month.

The following statement of plans for expansion of South Yuba Water Company is furnished by Resident Director Charles Van Norden:

1. To double the area of irrigation. The canals, at present, water about 10,000 acres, in and about Newcastle, Penryn, Loomis and Rocklin, but along the lines and before the terminals lie 200,000 unimproved; and at least half of these are, for location, soil and climate, desirable. The company is now engaged on a new canal line, destined to double the area under intensive cultivation. This is a continuation of the old Bear Valley and Dutch Flat ditch, formerly used to supply the monitors in the extensive hydraulic mining practiced throughout that region. It will bring a large stream—if necessary, 3000 inches—through Colfax to Clipper Gap, and will be very direct in its course, following the crest of a ridge and crossing declines by means of flumes and inverted siphons. At Clipper Gap this canal will empty into Auburn canal; while the flow from Bear river through the Auburn will be turned into the old Fidler's Green ditch, now renewed and enlarged. The latter will follow the ridge between the Auburn ravine and the North ravine; this, in size, will be seven feet wide at top and four at bottom, with a depth of three feet. The entire cost anticipated is \$50,000.

2. It is designed to supply Rocklin with water for municipal purposes and household use, under pressure, through a pipe line from the village of Loomis, which latter place is already provided for. The conduit will be 11 inches in diameter, and will empty into a village system of distributing pipes. The cost can hardly prove less than \$12,000.

3. It is the purpose of the company also to furnish Newcastle, Penryn, Loomis and Rocklin with electric lights. To the east of Newcastle a drop in a canal of 500 feet renders the development of many hundred-horse power feasible, and this will be utilized. The extreme distance of transmission is ten miles. The number of lights likely to be taken is 1000. The approximate cost is \$20,000.

4. The officers of the company are daily expecting instructions to proceed with a power-transmission scheme at Grass Valley. Southeast of this place a canal drops from the summit of the ridge to the bed of the Little Greenhorn creek, falling 500 feet in short distance. An electric station is to be built in the valley and 500-horse power transmitted along a pole line six miles long to a circle of needy mines. The precise route of the mine has not yet been decided upon.

5. Power will also be supplied the village of Colfax for electric lights and for factories on demand.

6. It is intended to erect a dam at the foot of Bear valley for storage; also a dam somewhere between Auburn and Newcastle, for storage and for regulation of distribution in the irrigated district.

7. The South Yuba has at disposal a vast amount of horse power running to waste at Newcastle, Auburn and

above, which sooner or later it hopes to utilize for factories, and it is prepared to bid very low to secure their installation.

8. The Fall Creek lakes, six in number, recently purchased, and the Omega lakes, three in number, also recently acquired, will with restored ditches, flumes and dams be connected with the great distributing reservoir (Lake Spaulding) above Bear valley.

The California Mining Exhibit.

Such progress has been made on the California mining exhibit at the Midwinter Fair as to render it certain that it will be the finest collection of ores and minerals ever made in this State, and probably in the United States. It will excel the mining display made at Chicago. Superintendent Edward H. Benjamin has worked very hard to make the exhibit a success.

Minerals approximating \$100,000 in intrinsic value have already been received. Other specimens are coming. The list of counties which will be represented on the floor of the Mechanic Arts building is given by Mr. Benjamin as follows: Shasta, Butte, Siskiyou, Calaveras, Santa Cruz, Amador, Plumas, Sierra, Nevada, Placer, Mariposa, Santa Clara, Kern, Tuolumne, Inyo, Mono, Contra Costa, San Bernardino, Santa Barbara, San Diego, Alameda, Napa, San Luis Obispo, Merced, Ventura. Nothing has been received from Trinity county, where the snow is three feet deep on the easiest road leading out of the mines.

Nevada county will make the largest exhibition of ore. A huge globe stands in the center of the Nevada county space, representing the bulk of gold which has been taken out of Nevada county alone. The globe is now white, but it will be gilded to make it look like gold. The bulk of gold which it represents is said to be worth \$205,000,000.

Sierra County will have an obelisk representing the amount of gold produced in that county alone, the value of the product being estimated at \$180,000,000.

Tuolumne county will have a revolving show case made of native woods, furnished with incandescent lights and containing gold specimens worth \$8,000.

Shasta county has an exhibit representing, by specimens, 142 mines in that county.

Amador county is at work constructing a tunnel which will show the geological formation of the mineral-bearing rock and all the realism of an actual mining tunnel.

Plumas county will have most of its exhibit which was at Chicago and which was a premium winner at the Columbian Exposition. It will be very handsome.

The most valuable display, intrinsically, will be made by Placer county, which will consist principally of fine gold specimens.

Santa Cruz will have a very interesting exhibit, embracing minerals and also fossils and curios.

Santa Barbara will show among other exhibits the largest block of asphalt ever quarried, weighing over four tons.

The State Mining Bureau will have a large exhibit, placing in position the pick of its attractive collections.

Siskiyou will exhibit for one thing its pictured rocks, on which there are landscapes imprinted by nature. One of these rocks has a picture of a lake and a perfect shadow of a forest and hillside. The tall trees have long shadows and the short trees have short shadows in this remarkable natural product.

Mariposa's exhibit will be small, but will contain some fine ores, among them being remarkably fine specimens of asbestos.

Butte has a fine display, auriferous gravel, quartz, talc, kaolin, chalk, limestone, fossils and Indian relics of past ages being included.

Santa Clara exhibits cinnabar and quicksilver. Quicksilver will also be exhibited from the Altoona district in Trinity county, and the two sections will furnish a lake of quicksilver on which cannon-balls and other heavy objects will float.

A space is reserved for valuable gold specimens, which will be exhibited handsomely arranged in show cases. Exhibits of this sort which are already received are included for the present in a large safe in the Mechanic Arts building in the mining section. Among the exhibitors are the following: L. M. Simon & Son, Scott Bar, Siskiyou county; Red Point drift mine, Placer county, principally crystallized gold; Power & Doolittle, Placer county, native gold and cement gravel; Mayflower mine, Forest Hill, Placer county, gold-bearing cement gravel; Morning Star mine, Iowa Hill, Placer county, native gold. Other exhibits of this sort are to be unpacked.

Beautiful specimens of travertine will be forwarded for the exhibition by Mr. Lindley of Mono county, who will exhibit something like 40 slabs about 4x6 feet in size. There are only two other quarries of travertine known, one being in South Africa and the other in France. Travertine is a very valuable building stone, examples of which are in the Mills building.

Napa county makes a fine exhibit of magnesite. A valuable discovery was recently made in Childs canyon. In Pennsylvania the deposit would be almost invaluable.

Alameda county will exhibit marble, manganese, carbonate of magnesia.

One interesting exhibit will be diatomaceous earth from Shasta county, a deposit of which was only recently discovered.

Nevada county's exhibit will include copper and copper products.

Calaveras county has a very fine display of free gold and copper ore.

Plumas exhibits, amid other products, native copper which can be cut with a cold chisel.

There is also to be seen native and magnetic iron from Shasta county. There is said to be a whole mountain of it on the McCloud river. In the Shasta collection there is a specimen of stalactites or iron drift from Charles Camden's mine, which will attract more than passing attention. It contains gold, silver and copper. It is almost pure iron.

A perfect fossil shell will attract attention in the Siskiyou county display.

The Kennedy mine, in Amador county, exhibits a pyramid of iron.

At one end of the State mining exhibit is the James Lick bronze statue, embracing the figures of three typical miners. This stands on a stout framework of timber, but the framework will be covered with slabs of handsome marble, which will constitute the exhibit of the Inyo Marble Company. At the other end of the exhibit is the facade which was shown at Chicago and which embraces for its materials marbles and other leading building stones of California.

Enough can be seen to warrant the assertion that the mining exhibit of the State will be remarkably attractive as a spectacle and very instructive even to many who are passably familiar with at least a part of the resources of California.

New Method of Treating Ores.

J. R. Moffitt of Stockton is the inventor of a new process of treating free-milling and refractory ores. The claims advanced for the process are:

First, the rock-breaker, which breaks up the ores, then the heated trough, through which the ores pass, drying as they go through to the pulverizer. It is necessary that the ores are heated to a certain degree for oxidizing and releasing the precious metals. This part of the work is done in the cyclone furnace; the granulated material passing within is banked in the rotating cylinder, which is heated by the wood fire under it, in a closed housing, with air pressure, to a red heat. The inner air cylinder has a number of troughs, each having a great number of blow-pipes, passing with increased motion with the outer cylinder, and having air valves to increase the air pressure in the blow-pipes. When these troughs are filling with the material of pulverized ores, and it being a red heat caused by the heated cylinder before mentioned, the blow-pipes at once cause a very high degree of heat in the material ascending, sufficient to volatilize and release from the precious metals all alloys or whatever combination may be therein. The cyclone motion given to the materials causes at once a perfect separation, oxidizing and forcing the gases to the upper tank of water, and under it to any depth desirable, the pipe being perforated, the air, etc., pass out of the water, much like a heavy mist, after the precious metals and materials, by their gravity, have passed down to the new device of the amalgamator—the material having passed through as described appears at this point very much like ashes. It is then passed on through the concentrator to a conveyor taking the tailings to the oxidizer, to again be treated. With the Moffitt system ores of the most rebellious nature are by atmospheric pressure and the high degree of heat, profitably worked. In ordinary cases, two tons per hour can be worked with this system at a less expense than any other system, and with less room and power, a simple shed being all that is necessary. The machinery is easily and cheaply transported.

THE Austin Reveille says that 70 men are employed at the Union, 17 at the Big Tunnel and about 100 men altogether by the Austin Mining Co. On the 15th of January the company paid out \$12,000 for December, 1893. The Big Tunnel is 8x8 feet, is now in 1500 feet and is being advanced at the rate of 200 feet per month. Two machines driving Ingersoll drills are run day and night. In the Union mine there is, on an average, 200 feet of new ground broken every month. The company is sinking a new shaft 300 feet between their office and the concentrator ore house. This shaft has been named the Cox shaft and is being sunk by James Roberts and Harry Harris.

Nickel-Steel in the Arts.

Extract from paper read before Colorado Scientific Society by W. L. Austin, Ph. D.

The price of nickel has been falling for several years, so that now, with the improvement in methods of producing the metal and its alloys, we can confidently expect to see its cost steadily reduced until it finds a ready entrance into the steel trade for other purposes than making armor plates and guns.

There is naturally some hesitation in using it, as is the case with any untried material, in places subject to great strains and extremes of temperature, such as occur in boiler plates, bridge building and marine engineering. A great many experiments must precede its adoption for such

that is, when the hole is large enough to admit a mandrel, and when so treated they are essentially improved. Nickel-steel shafting will not be altogether a novelty, however, for during the past summer the Bethlehem Iron Works completed a spare crank shaft for the American Liner, Paris, using nickel-steel of about 90,000 pounds tensile strength, which is said to be 25,000 pounds in excess of any shafting made by German or English manufacturers. This statement is, however, open to some doubt, for an English firm, which for a long time enjoyed an enviable reputation for the excellence of its shafting, owed its success, it is claimed, to the small quantity of nickel introduced into the steel used for that purpose. But this was before nickel-steel had begun to excite general interest.

The possibilities opened up before ship-builders and

The Midwinter Fair as It Is.

There appears on this page a view of the site and buildings of the Midwinter Fair as they actually appear, or, rather, as they appeared about two weeks ago, when the photograph was taken. Such a view is more satisfactory than the ideal bird's-eye view of the artist, because one can be sure of the truth of the machine. The view shows that the statements made of the extended and varied architectural features of the fair have not been exaggerated. Of course the point of view gives a close budding of the structures which does them discredit, because they have really large and well-ornamented interspaces and landscape garden effects, but otherwise it fairly presents the main features of the scene. Beyond the fair grounds

VIEW OF THE MIDWINTER EXPOSITION GROUNDS AND THE GOLDEN GATE. (From a Photograph.)

purposes, but when it finally wins the confidence of the engineers, and some rational and cheap method of reduction from its ores has been introduced, we may expect to see the consumption greatly extended and the production keep pace with the demand.

Very little has been published regarding the use of nickel-steel in the arts and manufactures. It is, however, quietly being experimented with. Last year it was decided to place sections of nickel-steel propeller shafting in the United States protected cruiser Brooklyn, and Battleship No. 1 (the Iowa). The ordinary carbon-steel used for such purposes has a tensile strength varying from 60,000 to 65,000 pounds per square inch, whereas the nickel-steel intended for the shafting spoken of will show a tensile strength of 90,000 pounds per square inch, the elongation being in both cases about the same—20 degrees. Using this stronger steel for the purposes specified will warrant removing the interior metal by boring, thus materially lessening the weight while preserving the efficiency. Such bored-out castings may in some cases be hollow forged—

architects when a steel is obtainable by them with over 100,000 pounds tensile strength and an elastic limit in proportion, without seriously impairing elongation or reduction of area, have a tendency to lead into flights of fancy which it is premature to indulge in before this material has stood the test of prolonged usage.

By preparations for war the arts of peace are advanced, and to the navy department of the United States is largely due the practical development of the most valuable qualities to which the metal nickel can lay claim. In the probable extension of this at present almost wholly war material into the arts and manufactures lies the main hope of nickel in the immediate future.

E. B. WAGY, one of the syndicate interested in the San Marcial coal fields of Sonora, has recently returned to Tucson. He states that two shafts have been sunk, one to the depth of 90 feet penetrating a six-foot stratum of pure anthracite coal, another to a depth of 35 feet penetrating a seven-foot stratum. The coal is of very high grade.

are the stretches of sand dunes which lie between its northern boundary and the shores of the strait known as the Golden Gate. Upon this narrow flow of water floats all the shipping which traverses bay and ocean from the port of San Francisco. Across the Golden Gate lies the shore of Marin county, and the elevations in the distance are those of the Coast Range, with Tamalpais as reigning crest, in the immediate vicinity of San Francisco. The picture has interest aside from its embodiment of the outer features of the fair, because it gives a view across the Golden Gate, while all conventional views are at right angles with this and show in profile the headlands through which, at some remote era, the great interior waters of California forced their way to union with the Pacific ocean. The fair grounds are picturesquely environed and the adjacent country should receive attention from the visitor.

It ought to be mentioned that the electric tower, which rears itself from the grand court to a height of 250 feet, is not shown in the illustration. The tower has now been reared and will be one of the most conspicuous features.

An Address in Favor of Good Roads.

The address to the people of Sacramento county by the committee which has in charge the bonding proposition for the construction of good roads, is significant in all California counties, and for this reason we present the following portions:

The Executive Committee of the County Road Convention solicits the electors of the county to sign petitions to the supervisors, to submit to the people the question whether they favor a bond issue for 40 years of call bonds for \$500,000, at not over five per cent, for the construction this year of certain trunk lines of permanent highways in macadam.

The estimated aggregate length of the roads is about 156 miles, to be in tracks of 16 feet, and built under the supervision of competent road engineers and by contract.

It is local option in perfection; it is bringing government near to the people; it is the right way to determine such questions before beginning active work.

All the assessable property in the county is liable under such a scheme. Sacramento electors within town and city limits propose to share quite half the burden, thus enabling the whole people to join in the work, since all the people will reap the benefits.

Road-building is of two kinds—temporary and permanent. The earth and the gravel roads are of the first, macadam of the second class.

A Macadam Road Explained.—A macadam road is made by first preparing the earth with but a slight crown, or rounding, with as little disturbance of the soil as may be; then it is rolled by improved machinery thoroughly. Next is laid on about seven inches of coarse broken trap-rock, of which broken cobble is a high order and is plentiful. The interstices are then filled with smaller broken road metal, and the whole again rolled hard and smooth. Then is put on six inches, more or less, of fine broken stone, and that is dressed with stone dust or pulverized rock, and the whole rolled hard and smooth, creating a water-shedding roof, commonly called a "surface."

In brief terms, that is a good macadam road, and with little care will not alone last hundreds of years, always smooth, clean and offering least resistance to wheel or hoof, but it increases speed of movement, lessens wear and tear, and adds threefold to all hauling capacity.

All testimony everywhere is that such roads are the cheapest. In the interest of economy they ought to be built on a systematic and comprehensive plan, and not by a hand-to-mouth and long-delayed doing by piecemeal, for the latter process destroys system, postpones benefits many years, and gives no assurance of continuance of the work from one administration to another.

While these 156 miles of trunk roads cannot reach to every man's door, they will make the main lines, around which a branch system will grow up. To every man they will offer just so much mileage of good road as he now has to cover on bad road on reaching main line and going thence to the common center—the county seat.

Vast Sums for Patchwork.—The cost of systematic construction is most just when distributed over a long period and put in part upon those to come after us, who are to be the greatest beneficiaries.

The interest paid comes back many fold in the benefit gained. Raising some \$40,000 a year for road purposes, Sacramento county, in 40 years, if she goes on under the present system, will raise by direct tax the enormous sum of \$1,600,000, and will have to show for this great outlay of money only such roads as she now has.

Taxes Will Really Be Lessened.—Under the bonding plan, which is not new, but has been proved by trial elsewhere, the entire cost, distributed over the same period, will be \$1,062,500, principal and interest, and meanwhile we will have all the uses and benefits of the macadam system.

We append a table showing this in detail, but take note that therein no account is made of the certain increase of values by reason of the work proposed; also, the calculation is made on the basis of \$34,000,000 of assessment roll, city and county, whereas we venture the statement that within five years the assessment roll will increase to \$40,000,000, and within ten years to \$50,000,000 by reason of this needed improvement; hence the tax will go down.

The present road tax is 25 cents on county property only, and all agree will never be less under the old system, that which we have pursued for the past 40 years.

But under the new it will not, after the completion of the new trunk lines, be so great, because the enormous cost of maintenance of present roads will be reduced (to the extent of 156 miles, or so much as we can build with the fund) to less than one-third the present cost of maintenance. This is seen when we tell you that there are 400 miles of road in the county; the new macadam will absorb within 44 miles of half of all these roads. So we estimate that the present road tax will not be increased, certainly not after the roads are completed, and that pres-

ently it will pay the interest, the principal and the cost of keeping all the other roads as now cared for. Probably it will decline very early, since the assessable values must increase under the new system alone and the cost of maintenance decline accordingly. If the new system is adopted, no more tax money will go into the trunk lines under the old system, and these lines now absorb seventenths of all the money spent on roads.

We cannot now enlarge to you upon the benefits of the proposed scheme. Aside from the confessed advantages of it to all people of the county, whether on the trunk lines or somewhat removed, it will put into circulation in the county a large sum greatly needed, and in its expenditure our own people and those with families will be preferred. The work will be done with proper machinery, which the county can own for further use, under competent engineering supervision and with all the care and circumspection possible to employ.

The proposed good-road plan not alone benefits the people living in the country, but must be of great benefit to the people living in the city. The country must first be prosperous before the cities can thrive. Increase in population and in prosperity in the country means increased value to city real estate, increased business for the shopkeeper and merchant, increased and more steady labor for the wage-earner. Hence, if the owner of city property wants his lots and his houses to be worth more money, if the city shopkeepers and merchants want more customers, if the city wage-earners want steady employment and more of it, it is to their interest to help along this movement, which, as shown in other counties, must add to the wealth and prosperity of the entire county, and must place Sacramento county in the front rank among the progressive counties of California.

History of One Cœur d'Alene Mine.

The sale of the Morning mine of Mullan by Receiver Schley for a consideration aggregating \$251,000, as reported in the press dispatches sent out from Milwaukee on Saturday, is the last of a series of transactions which have made that property one of the most historical mines in the Cœur d'Alenes, says the *Spokane Review*. The Morning is a low-grade property, but it was once worked to considerable pecuniary advantage by its owners. The complicated series of transactions of which it has been the subject for the past three years began with the suspension three years ago of the Spokane National Bank and the Hussey Banks at Wallace and Mullan immediately afterward.

At the time of the bank failure there was a first mortgage on the mine, amounting originally to \$100,000, which had been reduced to \$54,000, held by Head of Chicago, and known in subsequent deals as the Head mortgage. A second mortgage, to secure \$100,000, held by the Spokane National Bank, and liens and attachments subsequently placed on the mine brought its indebtedness up to \$370,000. The liens included the indebtedness of the suspended bank at Wallace to the county of Shoshone. When Herman L. Chase assumed the receivership of the Spokane National Bank, negotiations were set on foot to sell the mine. They were involved in almost endless difficulties, because it was necessary, in order to pass title, to lift some of the claims. All of the holders in turn declined to release their claims, and it became apparent almost from the start that no first payment within reason would be sufficient to take up \$370,000 worth at once.

The mine was finally sold to a syndicate organized as the Morning Mining Company of Milwaukee, the consideration being \$400,000, half in cash. Receiver Chase then made a proposition, as receiver of the bank, to release the second mortgage held by the bank, on condition that others would release their claims for the purpose of passing title. The company, in turn, agreed with the receiver to expend not less than \$100,000 within six months for permanent improvements. The improvements were specified—a concentrator of a daily capacity of 300 tons and a railroad to the mine. Receiver Chase also took a first mortgage in lieu of the money he was to have received on the original second mortgage, to the amount of \$200,000. The terms of the remaining payments were dictated by the receiver. There were three equal payments in all of \$66,666.66 each. The first matured Oct. 1, 1893; the second will fall due April 1st of this year, and the last a year from the first. The notes were, in turn, cut in three parts for convenience in subsequent negotiations and were of the denominations of \$20,000, \$20,000 and \$26,666.66. All the notes were discounted in the East, in various quarters, and the money thus obtained was devoted to paying much of the 90 per cent dividend subsequently declared to the depositors in the Spokane National Bank.

The mine then entered, in common with the rest of the Cœur d'Alenes, upon a period of depression. First came the labor troubles and then unfavorable legislation, which forced the prices of silver and lead down to the lowest

notch. The mine failed to earn even the interest charges accruing against it, and defaulted the first ones due. Under the terms of the mortgages, the noteholders applied for and obtained a receiver. For the same reason that the purchasers could not make the mine pay, the receiver failed to, and the court ordered the receiver's sale, under which the latest transfer of the series was made last Saturday.

The new purchaser, Charles F. Pfister, represents the largest owners, and the sale practically amounts to a transfer from the original purchasers to themselves, with a consequent freeing out of the small fry of the original corporation.

The early efforts to dispose of the mine in such a manner as to bring the greatest amount of ready cash will some day make a volume in the history of western mining ventures. The mine was practically sold a dozen times, and the air was constantly full of rumors and contradictions, while the principals in the various deals were hovering constantly between hope and fear. The first sale was made to a syndicate organized by the intrepid adventurer, Jim Wardner, the price named being \$750,000. The purchasers relied upon the expert judgment of General Her, the millionaire mine and smelter operator. At the critical period, however, labor troubles on the scene of his own investments kept him so busy that he failed to come to Idaho and the whole sale was frustrated.

Two mining men named Bratenober and Wertenweiler then negotiated for the Morning mine on behalf of an English syndicate, the price finally agreed upon that time being \$700,000. Bratenober made his reputation in the Drum Lummond of Montana, and his partner—Wertenweiler—was a California expert, a consort and confidant of such well-known magnates as the Hearsts, the Mackays, Jim Flood and Lucky Baldwin. There was trouble about arranging the terms. The syndicate wanted too much time for the first payment, and the others were anxious to obtain a considerable sum of ready cash. So that transaction fell through, and the Bratenober-Wertenweiler syndicate purchased the famous De Lamar mine in southern Idaho. The De Lamar has since, under the direction of Manager Plummer, who was retained immediately afterward, paid dividends averaging \$50,000 a month clear. It was bought for \$2,000,000, on the terms of payment declined by those who controlled the Morning.

A German syndicate next negotiated for the property at \$600,000, and one day the contract was signed in Spokane, the papers all being duly executed. Financial troubles of their own caused the German gentlemen to withdraw. Capitalists of New York, Boston, Hartford, Conn., and other money centers were induced in turn to consider the proposition, and in turn the deals were defeated by difficulty in obtaining enough ready cash. The final sale was made under some pressure, but it met the primary requirements of the receiver of the bank in almost every particular.

But the Morning mine is to this day considered a splendid property if prices of lead and silver ever come to be restored. "There is enough ore in sight," says a well-known mining man of the Cœur d'Alenes, "to pay for it. If lead were worth anything at all, the Morning would be all right. You can measure enough ore with a two-foot rule to pay for it; and if favorable conditions ever come back to us, it will take but a few weeks to put the property on a dividend-paying foundation once again."

PAPERS in a suit to establish the ownership to the waters of Santa Ana river have been served at Riverside. The suit is brought by the Anaheim Union Water Company and Santa Ana Irrigation Company, both corporations of Orange county. The two companies lay claim to 12,000 inches of water running in the Santa Ana river; and it is to have this claim established that suit has been brought.

ALL the arrangements for the running of the Canadian Pacific trains through to Seattle over the Great Northern coast lines, which begins February 1, have been completed. Not only will Canadian Pacific cars run through to that city, but the first-class train of the Great Northern will run through Vancouver.

JUDGE VIRDEN, of Mono county, decided that sheep may not be watered in a creek which had been used for irrigating purposes by a rancher near Bridgeport. His decision was sustained by the Supreme Court. The injunction against the sheep men was made perpetual.

F. L. LEONARD, a young man mining four miles east of Leland, Or., brought in a nugget of gold covered with quicksilver Wednesday. The value of the lump is about \$35. It resembles a piece of amalgam, though he insists the nugget is just as he picked it out of the ledge.

IDAHO capitalists propose to utilize the Shoshone falls of the Snake river to generate electricity to operate a railroad 40 miles in length.

Scientific Progress.

Submarine Photography.

One of the most interesting scientific experiments of recent years was the photographing under water done in the Red sea by Louis Boutan, the botanical lecturer in the Sorbonne, Paris. In the course of this submarine work, M. Boutan discovered many curious plants and fish which were absolutely unknown before, and which have been presented since by the sub-aquatic explorer to his classes. A few days ago M. Boutan discussed his novel invention with a New York World reporter.

"My experiment came about in this manner," M. Boutan said. "While making a course of researches along the shores of France and in the neighborhood of my laboratory at Banuyls-sur-Mer, I was struck with the beauty of the deep-water fish that it was really impossible to put in an aquarium where scientists could study them, for the reason that so soon as they were brought into shallow water or taken into the air their beauty faded and their entire form appeared to undergo a physical metamorphosis that was destructive of their beauty of outline and shape. Therefore I resolved to try to preserve their perfect form by means of photography.

"At first I endeavored to make the picture by the aid of the light that penetrated the water, but while this is considerable I found that below a certain depth, and that a very moderate one, this light was altogether insufficient, and so I was driven to the necessity of designing an apparatus for burning a magnesium light under water that would provide me with the artificial sun required.

"This apparatus consists of a tank filled with oxygen and surmounted by a glass globe containing an alcohol lamp. On the flame of this lamp is thrown, by means of an automatic arrangement, plinches of powdered magnesium, producing a powerful, almost blinding light at the moment the camera is snapped to take the picture. The lower end of the tank is pierced so as to admit the sea water, which takes the place of the oxygen, as the latter is gradually consumed, and thus the steady, regular pressure is preserved.

"Armed with a machine constructed after this fashion, I sought the most picturesque site possible at the bottom of the Red sea and made by negatives.

"From beneath almost every rock I saw the long tentacles of some species of devil-fish, or octopus, feeling around in the water, seeking to seize an unwary fish that might venture too close to the repulsive object. Fortunately, perhaps, for me, I saw none of these creatures with tentacles longer than 36 inches, and therefore I was not interfered with in any way by them.

"But several such lights as that, with an occasional monster even more repulsive than these are, robbed the place of much of its beauty, and frequently drew my startled attention so abruptly from the pleasing surroundings as to make the contrast very marked. Sometimes these repellent objects would persist in swimming about me to such an extent that I was forced to attack them with a stick or cane I had, and then they would flee to the protection of the rocks."

Variability of the Wind.

Dr. Langley of the Smithsonian Institution advances a new theory as to the nature of wind which he thinks goes a long way toward determining the ultimate possibility of mechanical flight. The wind is not, the doctor says, even an approximately uniform moving mass of air, but consists of a succession of very brief pulsations, varying in amplitude, and, relatively to the mean movement of the wind, in direction also. Once launched into the mean velocity of the wind

a flying machine, therefore, if it had the power to vary its inclination, could take advantage of the varying velocity and direction of the wind. Falling with the slower wind it would accumulate the energy which it would have to expend in rising with the higher, and thus become capable of indefinite sustenance or advance. It would require, however, an even more intimate knowledge and quick perception of the currents of the air than a mariner possesses as to the currents of the sea.

Explosiveness of Coal Gas.

In the use of mixed gases for lantern purposes the question sometimes arises as to whether coal gas or pure hydrogen is most readily exploded in case of a rise of temperature. An important contribution to our knowledge has recently been made by Professor Victor Meyer. It was found that with pure hydrogen and oxygen the initial temperature required to cause explosion varied between 612° and 686°, no difference being found whether the gases be dry or moist. The presence of platinum foil prevented explosion, quick combustion always took place even when a temperature of 715° was reached. When hydrocarbons were used with oxygen it was found that the temperature needed to induce explosion was lower the greater amount of carbon present. Thus the mean temperatures of explosions with methane, ethane and propane were 657°, 616° and 547° respectively. It will thus be seen that whatever the difference may amount to in practice it is a fact that pure hydrogen and oxygen will be more difficult to explode than mixtures of coal gas and oxygen.

Chromium and Aluminum.

A new process has been introduced for imparting hardness to aluminum by the addition of chromium. In consequence of the difference in the fusing points of the two metals, certain precautions have to be taken to alloy them both, and if electrolysis is employed for the purpose, it is stated that one or another of the known methods can be used, and the alumina, salts of alumina, cryolite, etc., treated direct with a determined quantity of salts or oxides, chromium, granulated chromium, or chromium in any other suitable condition.

Artificial Ice.

The Massachusetts State Board of Health concludes, from investigations of artificial ice, that artificial processes of freezing concentrate the impurities of the water in the inner core or the portion last frozen; that the impurities are least if distilled water is used; that the number of bacteria in artificial ice is insignificant, under the prevailing methods of manufacture; and that the amount of zinc found in ice is insufficient to cause injury from its use.

How to Mend Crockery.

A correspondent of the *Scientific American* says. Before being allowed to get dirty or greasy tie all the broken pieces in their places nicely with any kind of string that suits, then put in an iron or tin dish that can be put on the fire, pour in as much milk as will cover the fractures well, put on the fire and boil for say ten minutes, and the whole operation is complete. Don't undo the wrapplog until the dish is completely cold, and if yours hold as ours do you will call it a success.

To Arrest a Cold.

Tincture gelsemium.....gtt. 2
Liquid ergot....." 5
Camphor water.....dr. 4

Mix and take every hour immediately the cold is felt. If this is taken for twelve hours, at the same time keeping indoors in the warmth, many a cold will be cut short.—Cor. Bl. Schweiz, Aertze.

Metallurgy and Ores.

SELBY
SMELTING AND LEAD CO.

416 Montgomery St., San Francisco.

GOLD AND SILVER REFINERY

—AND—

ASSAY OFFICE.

Highest Prices Paid for Gold, Silver and Lead Ores and Sulphurets.

—MANUFACTURERS OF—

BLUESTONE, LEAD PIPE, SHEET LEAD, SHOT, ETC., ETC.

—ALSO MANUFACTURERS OF—

Standard Shot - Gun Cartridges,
Under Chamberlin Patent.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

63 & 65 First St., cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoffers, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing the supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.

Agents of the Denver Fire Clay Co., and for the Morgan Crucible Co., Battersea, England. Also for E. G. Dennett's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of silver guaranteed. Orders taken at the lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

Assessment Notices.

OCIOENTAL CONSOLIDATED MINING COMPANY.
—Location of principal place of business, San Francisco, California. Location of works, Silver Star Mining District, Virginia, Storey County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors held on the fifteenth day of January, 1894, an assessment (No. 15) of Ten Cents (10c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the company, Room 69, Nevada Block, 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of February, 1894, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on WEONESSDAY, the 14th day of March, 1894, to pay the delinquent assessment, together with the cost of advertising and expenses of sale. By order of the Board of Directors.

ALFRED K. DUBROW, Secretary.

Office—Room 69 Nevada Block, No. 309 Montgomery street, San Francisco, California.

DELINQUENT SALE NOTICE.

STANDARD GOLD AND SILVER MINING COMPANY. Location of principal place of business, San Francisco, California. Location of works, Butte County, California.

Notice—There are delinquent upon the following described stock, on account of Assessment (No. 1) levied on the 18th day of December, 1893, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Cert.	No. Shares.	Am't.
E. McGrath.....	32	500	\$25 00

PRACTICAL TREATISE ON HYDRAULIC
MINING.

By AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep places, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdies, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For sale by DEWEY PUBLISHING CO., 320 Market St., San Francisco, Cal.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for \$3 per volume of six months. Per year (two volumes) \$5. Inserted in Dewey's patent binder, 60 cents additional per volume.

Mechanical Progress.

Automatic Fog Signaling.

The latest attempt to solve the problem of automatic fog signaling is that which has been made by J. F. Dixon, who effects this object by an ingenious and practical mechanical contrivance enclosed in a deal casing about five feet square and standing a foot or so above the ground level, says the *Colliery Guardian*. It is placed beside the rails and connected up with the signal man. Like that signal, its normal position is at danger—that is, a fog signal or detonator is on the rail. In clear weather the detonator is withdrawn from the rail, and is kept clear of it by raising a lever and fixing it in that position, but when a fog occurs the lever is released and the detonator is placed on the rail ready for a passing train. The mechanism consists mainly of an arm fitted with a jaw or clip, which acts like a bird's beak the arm being capable of horizontal rotation through half a circle. In clear weather the arm, with a detonator held in the clip, lies parallel with the rail and pointing to the left. When a fog comes on, the fog man—who can attend to several sets of apparatus—is summoned, and he releases the lever. This brings the arm out at right angles with the rail, and the detonator is held on the top of the rail. When a train passes the spot the leading wheel of the engine explodes the detonator—or rather two detonators in succession, for the apparatus is in duplicate in order to insure against a misfire. Placed close beside the rail and within a few feet of the detonator apparatus is a long inclined lever, over which the flange of the leading wheel of the engine passes, depressing it. This lever is connected with the apparatus, and its depression causes the radial arm to swing round to the right and to enter the casing of the apparatus. As it enters, the jaws of the clip are made to open, and the case of the detonator is dropped into a receptacle. Proceeding a few inches farther on its travel, the clip seizes hold of a fresh detonator from the magazine, the arm slowly swings back toward the rail, and finally stops at right angles to it, holding the fresh detonator over the rail ready for the next train, which, when it arrives, passes over it and causes the cycle of operations to be repeated. The return of the clip to the rail is retarded by a very ingenious dash-pot, or air-cylinder, arrangement, which insures that the fresh detonator shall not be placed in position before the train has passed well clear of the point where the previous one was exploded. The dash-pot arrangement also prevents the lever from rising rapidly and being subjected to blows from the following wheels of the engine and train. When the fog clears up, the detonator is pulled off the line by the action of the danger signal, but it would be put on again when the signal was set to danger, unless the lever were propped up as already described, and this should be done by the fog man before he leaves duty.

Wood-Working Machinery.

Some ingenious devices in wood-working machinery have lately been brought forward, in especial a boring mechanism to be used in making holes for blind railing in hard wood floors, the working being entirely automatic; that is, the stock is carried forward by a fluted roll, and is stopped by a cam at proper distances from the boring of holes by the bit which works horizontally, the board being carried on an angle, says the *Manufacturer's Gazette*.

Another most useful and novel arrangement in this line is a hard wood flooring machine which takes the rough stock, planes it on both sides, and matches it; there are five cutting cylinders; the first having a flexible bar, which allows of the free passage of irregularities in stock, and insures the presentation to the cylinders of a uniform

surface, this being followed by top and side and bottom finishing cylinders; the side finishing cylinders are equipped with a weighted chip-breaker bar, which prevents splintering the stock; there are six feed rolls of 9½ inches diameter, and the back rolls are placed beyond the last cylinder, thus carrying all stock clear through the machine.

Steam Engines.

In a paper read before the London Society of Firemen and Engineers, the following ideas were brought out:

It is the province of mechanical engineers as the makers of the steam engine to produce a machine that will utilize with the greatest economy the fuel by which the steam is generated. Comparing the same engine with a well-constructed turbine water-wheel, the latter is found to be by far the most efficient, giving off an effective work of 75 per cent of the fall of the water, whereas the steam only produces 7½ per cent of the total effective heat produced by the combustion of the fuel in the furnace. The losses are represented by 40 per cent lost in causing of draught necessary for combustion. The remaining 60 per cent is given up to the engine to be turned into work, of which quantity only 7½ per cent is utilized.

According to theory, two pounds of coal should produce 7½-horse power, whereas in the best engines we get only 1½-horse power. These losses are caused by condensation and radiation in the cylinder passages. By the use of the condenser, which would not be required in an ideal engine, as in such an engine, the whole heat having been utilized, the water of condensation would be better drawn away. Compounding the engine has been a means of improvement, by enabling the boiler to work at high pressure, and give the engine, therefore, a greater expansion. But this can only be carried to a certain extent. To further improve the steam engine, a better means of burning the fuel in the boiler must be devised by forced draught, and raising the temperature and pressure as far as the material will safely permit, and by more economically utilizing the heat of evaporation through a moderate range of expansion in well-proportioned cylinders.

Stone Work.

Stone walls are measured by the perch (24½ cubic feet), says the *Clay Journal*. Openings less than three feet wide are counted solid; over three feet deducted, but 18 inches are added to the running measure for each jamb built. Arches are counted solid from their spring. Corners of buildings are measured twice. Pillars less than three feet are counted on three sides as lineal, multiplied by fourth side and depth.

It is customary to measure all foundation and dimension stone by the cubic foot; water tables and base courses by lineal feet. All sills and lintels or ashlar by superficial feet, and no wall less than 18 inches thick.

The greatest safe load on super. foot on
Granite piers..... 40 tons
Limestone piers..... 25 "
Sandstone piers..... 15 "
Brick work in cement..... 3 "
Rubble masonry..... 2 "
Lime concrete foundations..... 2½ "

The height of brick or stone piers should not exceed 12 times least thickness at base.

First Iron Bridge.

The first iron bridge ever erected in the world, and which is in constant use at the present time, spans a little river in the county of Salop, on the railroad leading from Shrewsbury to Worcester, England. It was built in the year 1778, is exactly 96 feet in length; total amount of iron used in construction, 378 tons. Stephenson, the great engineer, in writing concerning it, said: "When we consider the fact that the casting of iron was at that time in its infancy, we are convinced that unblushing audacity alone could conceive and carry into execution such an undertaking."

Useful Information.

Do Not Cough.

In all bronchial affections the paroxysms of the cough should be placed as far as possible under control of the will, says the *Youth's Companion*. The old idea that disagreeable sensations in the throat indicate the presence "something there which ought to come up" has been entirely displaced by the more rational view that the continued and prolonged efforts to expel that "something" are often productive of more mischief than would result from its being allowed to remain.

There is attendant upon every disease of the bronchial tubes a greater or less amount of mucus, which exudes from the membranous lining of the tube. Of course, there are the accompanying signs of inflammation—heat, pain, swelling and redness; but it is the mucus exudation which is for the most part responsible for the disagreeable sensation which we instinctively attempt to alleviate by coughing.

Now it is certain that, in a great majority of instances, where the general health of the patient is not attacked, this exudation undergoes what is called resolution; that is, it is re-absorbed through the fine network of the blood, where it is taken care of, and complete recovery is effected. On the other hand, let us suppose that we do not wait for the resolution to take place; but that, on the theory that every part of the exudation should be expelled as being of a poisonous nature, we strain to exhaustion every muscle of expiration, and, in fact the whole system. What follows?

We may have accomplished our immediate object, or the seat of the inflammation may have been out of reach. In either event, if we could see the point at which our efforts had been directed, we should discover that they had not been productive of the results anticipated. Instead of the inflammation being in any way allayed, we should find that an effect had been produced similar to that which follows scratching an itching sore. The irritation has for a moment been relieved, but it is only a question of time when it will return with renewed energy.

The habit of endeavoring to expel more of the exudation than will come away with gentle and infrequent coughing is an exhausting and idle one.

Purification of Resin.

One process consists of melting the resin and passing through it a current of chlorine gas, acidifying with sulphuric acid, washing with boiling water, and finally with hot water containing nitric acid, says the *Scientific American*.

Another process consists of melting and then boiling the resin with a saturated solution of salt. After boiling for some minutes in a solution of chromic acid or a solution of bichromate of potash with twice its weight of sulphuric acid, it is washed with a slightly ammoniacal water.

Another method consists in heating the resin with a mixture of chalk, dioxide of manganese and potassium bichromate and filtering through sand. Heating with powdered zinc, with or without sodium bisulphate, has also been suggested. Sulphuric acid and zinc chloride at high temperatures have also been tried.

Seemingly the best process consists of first filtering to separate insoluble matters and dirt, then heating to about 150° C. with five per cent of zinc chloride for an hour or two, and then adding 12 per cent of bichrome in the form of a powder. After sufficient heating, the mass is allowed to cool down to 100° C. and is filtered. Lastly we have to mention purification by anhydrous sulphuric acid with heat under pressure in a sheet-iron caldron which can be heated by superheated steam and fitted with a cover capable of re-

sisting a pressure of five kilos. to the cubic centimeter.

In this 100 kilos. of the resin to be purified are placed, heated to fusion, the pressure raised to four kilos. and the sulphuric acid added. The whole is heated to 100° C. for an hour, when it is left to cool, and washed with boiling water. The sulphuric acid process and the zinc chloride process are often worked in conjunction with each other.

The Humming Bird at Home.

While spending the winter in California, I made my first acquaintance with Madam Hummingbird "at home." In the first place the location could not have been improved upon. Just picture in your mind a lawn dotted with orange, lemon, fig and palm trees, with here and there a giant century plant, or bunch of pampas grass, and no end of flowers. While a cypress hedge, overshadowed by stately encalyptus and pepper trees, separated the lawn from the street. One day while gathering oranges, I was startled by the rapid and angry darting of a humming bird near my face, which led me to look closely in that part of the tree, which resulted after a little search in the discovery of my first humming bird's nest. It was placed on a twig not as large as a lead pencil, on one of the lower limbs of the orange tree, and it was so colored with lichens the same color as the bark of the tree that it was difficult to find it again even after I knew about where it was. The nest is about the size of the burr oak acorn cup, built almost entirely of the feathery plumes of the pampas grass, covered with green lichens, and all held together, and to the limb, with something greatly resembling spider web. Within this "marvel of construction" were two semi-transparent eggs, almost too small to describe, and my efforts to use the blowpipe on them blew them all to smithereens.

Before taking the nest, I visited Madam Hummingbird several times, and nearly always found her at home. She never left the nest but a few minutes at a time.—Frank Ford, Mag. of Nat. Sci.

Historic Battlefields.

At Cannae, where the Romans sustained the worst defeat they ever experienced, there were 140,000 men on the field, of whom 52,000 were killed.

At the battle on the Thrasymene, where Hannibal defeated the Romans, there were 65,000 men engaged, of whom 17,000 were killed.

At Gettysburg 140,000 men fought on the Union and Confederate sides, of whom 8000 were placed hors de combat.

After the surrender of the Turks at Plevna the Russians took possession of \$17,000,000 worth of arms.

At Borodino 250,000 French and Russians fought, and the dead and wounded numbered 78,000.

During the retreat from Moscow the French lost or threw away over 600,000 muskets.

At Waterloo there were 145,000 men on both sides, of whom 51,000 were killed or disabled.

There were 402,000 men on the field of Sadowa, of whom 33,000 were killed or disabled.

At Austerlitz 170,000 were engaged and the dead and wounded numbered 38,000.

At Gravelotte 320,000 men were engaged, of whom 48,000 were killed or wounded.

Morengo called 58,000 men into action, of whom 13,000 were killed or crippled.

At Bannockburn 135,000 men fought, and 38,000 were killed or wounded.

Powerful Crane.

The most powerful hydraulic crane at present existing is reported to be one at the Italian government arsenal at La Spezia. It is capable of lifting 160 tons.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen.
First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight riffling surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifflings also save very fine sulphurates and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

BOOKS ON ASSAYING.

By C. H. AARON.
Part I.—Gold and Silver Ores.
SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes thereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning.
The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt, will be very desirable in the hands of many.

Table of Contents:
Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Churning; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Oupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1889. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.
Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.
SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion; Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:
Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhard's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new, original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.
Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

GLADSTONE MINING COMPANY, C. J. Clark, M. E. Gen'l Supt. FRENCH GULCH, Shasta Co., Cal., Dec 12, 1891.
 MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIR: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the Frue in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for Twelve Months. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to mention. In order to give an idea of the work they are doing here I will state that the ore has varied monthly from \$5 to \$20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six foot Frue Vanner too highly, and it is the only table that I would have in my mill.
 O. J. CLARK, Gen'l Supt.

PATENT Double-Acting Cornish Plunger.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER.

AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, besides doing away
with heavy balance
bobs often carrying from 25 to 50 tons of balance
works with 25 per cent less power. First outlay about one-third less. Suitable to
any under or downright shaft.
Friction reduced to a minimum. Occupies less space in the shaft. Has been tested
about a year and proved to work satisfactory in every respect.
GUARANTEED TO GIVE SATISFACTION.

Special attention is called to this new feature in the drainage of mines and raising water generally, by which a continuous discharge of water is produced on the up stroke, instead of on the down stroke only, which is effected by very much less than one-half the weight of machinery now in use.
When the ordinary pump becomes too small for the work it can be replaced by the new one, using the same rod and column, and doubling the discharge of water, a most important advantage in small shafts where there is not room for a larger pump.

Apply to WM NANCE, Grass Valley, Nevada County, Cal.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SHUT DOWN.—*Ledger*: The South Spring Hill Company shut down its mill on the first. A few men will be continued at work prospecting in the Medium, a property recently purchased by the South Spring Hill Company. This is a severe blow to Amador, for, in addition to being thrown out of work, many of the men have as much as three months wages coming to them.

The Hardenburg people are engaged in improving their hoisting machinery, and expect in a few weeks to get to work at opening up the ledge they recently encountered, with as large a force of men as possible.

The miners in the Zeila have been compelled to lay off one or two shifts this week on account of water, which has kept the hoist so busy that rock could not be hoisted. The mill ran all the time, however.

Butte.

BIG MINING TUNNEL.—*Oroville Mercury*: It is stated that the big Stow mine at Forbestown will soon be drained by a tunnel which will be run in the hill below the mine, tapping the ledge at a probable depth of 1000 feet. The mine will thus be drained without the aid of pumps, and possibly the ore will be delivered through the tunnel, avoiding the necessity of hoisting works. The Stow mine has shown itself by development to be one of the most extensive and profitable on the coast. It will require an immense outlay to construct the tunnel, but when completed the mine will be worked at greatly reduced cost. Heavy machinery is now on the way to the mine for this purpose. Barley drills run by air compressors will be used. The length of the tunnel is not known exactly, but it will probably be no less than a thousand feet long.

Kern.

THE NEW PLACERS.—The Los Angeles Herald claims to have carefully investigated the new gold districts of Goler, Red Rock and Summit, northeast of Mojave, and from entirely trustworthy sources has gathered information which it prints, and of which the following is a summary:

"The influx of miners to Red Rock continues heavy. Many are disappointed, but many others make money. An instance occurred recently where a claim was purchased for \$6000, and the next day the buyers were offered and declined the same sum for a third interest. The present manner of working with dry washers is crude, but the owners are sure they will take out \$200,000, even with the present appliances. The wasteful method used is illustrated by the fact that three men worked on tailings from the dry washers and took out three ounces of fine gold in one day. Martin Stoddard is a miner who is doing well. He sold 24 ounces of gold at Mojave last week that he had taken out in a few days. His vein of pay dirt is from four to five feet thick. At Goler the Benson Bros. of San Bernardino have done well. They went to the camp a few months ago and have sold \$20,000 worth of gold already, and find their claim steadily getting richer. A. Johnson and his partner are also doing well at Goler. On one day of last week ten ounces of gold were cleaned up from his claim. Summit camp is east from Goler, and from there also good reports come. A miner named Van Slyke is working there with two partners. A person who was at the camp recently states that he saw the three men take out \$180 in three days. A part of this claim is leased to Bakersfield men, and in one day they were seen to take out eight ounces. Mr. Van Slyke reports that the miners at Summit are averaging \$10 each a day. It appears settled beyond question that these three camps are but parts of a very extensive and wonderfully rich gold field. When the water is brought to the district from Owens river by the canal now being constructed, it is probable that the output will be something astounding, for now but a portion of the gold—the very coarsest—can be got by dry washing."

Nevada.

THE GRANITE HILL.—*Telegraph*, Jan. 31: The Granite Hill Mining Company is operating in Wolf creek, just below Boston ravine. Recently 237 pounds of ore from the mine were shipped to the Selby smelting works in San Francisco, and the result was that the company has received a check for \$50.70. The ore shown to-day was of much better quality than that shipped. The mine is looking well and when the company gets through the granite they expect something very rich. Ore will be assorted and shipped to the Selby works as often as possible. The Granite Hill has plenty of water power at a very low figure.

MINNE BONDED.—*Telegraph*, Jan. 31: Last week the Sebastopol mine, located in South Grass Valley, was bonded to E. H. Baxter and others of San Francisco, and Ben F. Runnels of this place. Active work will be commenced upon this valuable property on or before the first of May. The company proposes to erect machinery and to sink a new incline shaft to the depth of 300 feet.

ANOTHER MINE BONDED.—*Transcript*: J. J. Meacham has bonded his quartz mine on Piety Hill to a company that is now running a tunnel from the Weiss fish pond into the hill. Up to this time upward of \$15,000 has been taken from the mine above water level. The present company is pushing the work of development and it is believed a big property will be opened up there.

A GOON LEDGE.—*Grass Valley Union*, Feb. 1: There has been a decided change in the appear-

ance of the ledge at the St. John mine for the better during the past two weeks. Some of the quartz was brought to town yesterday and was pronounced by competent miners to be good milling ore. It is identical in character with that of the Idaho mine in the 400 level, and as in that mine at the same depth the ledge is very large, averaging about six feet. The ledge is encased between two beautiful walls, and is being drifted on in the 500 level.

JACK RABBIT TO START.—*Telegraph*: Superintendent Steinger of the Jack Rabbit mine informs us that he has a letter from the company's headquarters, to the effect that work would be resumed upon the property as soon as the roads were in condition to admit of hauling. The company propose sinking a new shaft and will also place new machinery on the property. The machinery will be run by water power. The Jack Rabbit is situated near the Buena Vista slide and no avoidable delay will be made in starting the work.

NEW SOURCE FOR WATER.—The Nevada City Transcript is informed that the Providence Mining Company has in contemplation a project for obtaining their water power from the South Yuba Company's ditch at Town Talk. The water will be conveyed by ditch and boxes part of the way, and then by pipe direct to the mine. By this arrangement a greater pressure can be obtained than at present, and the power can be distributed to better advantage. Besides this, there are other important advantages to be gained by making the change.

The Providence mine is looking better than for years, in fact it never looked better, and handsome cleanups are being made right along. The present company are working the mine systematically, and the good results of the development work done thus far are very flattering indeed. A rich and extensive shoot of ore has been found in the old Williams ground, from which quartz enough can be taken to keep the 40-stamp mill running steadily for a long time to come. This ledge is not the one now in dispute between the Champaign and Providence Companies, and in the event of a decision adverse to the latter company in the suit pending in the U. S. Circuit Court, it will not seriously interfere with operations in the mine. The Providence has a new lease of life, and there is every indication of a bright future for the old mine.

Sacramento.

CLAIMS TO HAVE A BONANZA.—The Bee's Folsom correspondent sends the following: David Blower, a rancher who resides about two miles from Folsom, came into town to-day and displayed samples of wonderfully rich gold-bearing cement and lava. He claims to have discovered a bank of rich deposit which extends ten feet in height and assays the same throughout. The samples really sparkle with gold. Rough estimates place the value of the cement all the way from \$40 to \$1000 a ton.

The deposit was found on the land of John Cardwell, which is protected by an agricultural patent and can be mined only by the owner.

Shasta.

A SALE.—*Democrat*: Barney Conroy has sold the Flat Creek quartz mine, formerly known as the Murray-Conroy mine, to Messrs. Hockett and Anderson for \$6500. Upon passing of deed, \$1100 was paid down and the balance will be paid in quarterly payments. This is a fine piece of mining property. The vein is small, but the ore is exceptionally high grade. The new owners will, in a few months, have a five-stamp mill in operation on the property.

Siskiyou.

VERY HIGH WATER.—*Yreka Journal*: The river miners on the Klamath are already making calculations for extensive operations next spring and summer, the exceedingly high water this winter cleaning out the stream in good shape for getting down to bedrock easier when the stream reaches the low-water mark.

There is about six feet of snow at the Boyle quartz mine, on the head of the north fork of Humboldt creek, and proportionately less all the way down to main creek, where there is but a few inches. This deep snow, high up on the mountain, with the ground thoroughly soaked from the heavy rainstorm, has compelled most of the companies working claims to shut down temporarily, on account of too much water in the shafts and tunnels. The snow and abundance of water, however, is much better for future success than a scarcity of water.

There is about 2½ feet of snow on the Deadwood mountain road at head of Greenhorn, with still greater quantity on the higher points, which will prove a good fountain in supplying water for ground sluicing on Cherry creek and also for quartz mining on Greenhorn and McAdams creeks.

Trinity.

MEN SCARCE.—*Journal*, Feb. 3: F. P. King has received a contract from the La Grange Hydraulic Gold Mining Co. to cover and line a portion of their new ditch and to keep it in repair for fifteen months. He has been employing all the men he could get during the last few days and there is no excuse for a man to be idle who is willing to work. Up to this time Mr. King has been unable to get what men he needed.

NEVADA.

Washoe District.

FOR AIA AND EXIT PURPOSES.—*Virginia Chronicle*: The Consolidated California & Virginia Company has begun opening the 1000 level north drift in the Best & Belcher from the Bonner shaft. This drift is some distance west of the course of the 1000 level southwest (Rule) drift from the Consolidated Virginia shaft, and when the former is reopened to the Best & Belcher north boundary line it will be extended in a northeasterly direction to connect with the Rule drift.

This work is for the double purpose of making an air connection and to provide an outlet for the underground employees of both mines in

case of an accident barring their exit to the surface through either the Consolidated Virginia or Bonner shaft. Since the Gould & Curry disaster, in which 11 men lost their lives through the lack of such an outlet, the management of Comstock mine have made connections with the underground workings of adjoining properties to provide more than one exit for miners to prevent the recurrence of such a calamity.

SUMMARY OF COMSTOCK OPERATIONS.—Following is a synopsis of the weekly reports from the Comstock mines for the week ending Feb. 3:

Consolidated California and Virginia, 1650 level.—In our workings in and from the drift run north from the foot of the upraise which was carried up from the sill floor of this level we have extracted a few tons of ore of average assay value. The drift running from east crosscut 1 from the drift run north from the winze (down 52 feet), at a point 40 feet north from the winze, has been advanced 13 feet; total length, 198 feet; face carries narrow streaks, from which we have extracted a few tons of ore of milling value. East crosscut 2 from the drift run north from the winze (down 25 feet), at a point 126 feet north from the winze, has been advanced 52 feet; total length, 97 feet; formation consists of porphyry, clay and quartz of low assay values. Total quantity of ore extracted from the mine during the week was 75 carloads, about 74 tons, averaging \$27.28 per ton. The largest portion of this ore came from our workings in the vicinity of the winze (20 feet down). The southwest drift (the Rule drift) from the 1000 station of the Con. Virginia shaft, has been advanced during the week 65 feet; total length, 518 feet; face in porphyry, clay and quartz of nominal value. This drift has been run from the shaft toward its objective point without any deviation from the original line which was laid down, and we have continued the work of reopening and extending a drift from the Best & Belcher side, which will meet the Rule drift at that objective point—a connection which will ventilate the workings and facilitate future operations in that locality.

Ophir—1465 level.—The drift running north from the crosscut running west from the main north drift on the sill floor of this level, at a point 124 feet south from winze station, has been extended 18 feet; total length, 107 feet; face in porphyry and clay separations. An advance of 100 feet has been made during the week in reopening and retimbering the central tunnel, making the total length of the drift reopened from its mouth 445 feet. Have continued (jointly with the Mexican Company) the work of making repairs to the main shaft.

Mexican—1465 level.—The crosscut running west from the drift run south from the top of the upraise which was carried up 45 feet above the sill floor of this level, at a point 40 feet west from the main north drift and 100 feet north from the south line of the mine, has been extended during the week 20 feet; total length, 180 feet; face in porphyry carrying clay separations.

Union mine—900 level.—The Union Con. and Sierra Nevada joint east crosscut near the north line of the Union mine, started from the joint south drift which was run from the joint west drift at a point 150 feet west of the shaft, has been extended during the week 25 feet, passing through hard porphyry. It is now entering softer ground.

Andes—420 level.—North drift from west crosscut 2 advanced 5 feet in low-grade quartz and stopped; total length, 37 feet. South drift from west crosscut 2 extended 14 feet in quartz of low grade and discontinued. A new crosscut will be started the coming week.

Best & Belcher—200 level.—East crosscut 4 started in northwest drift 170 feet from our north boundary has been extended 13 feet and discontinued with face in hard porphyry; total length, 28 feet. 900 level.—The east crosscut which is being run on our south boundary has been advanced 12 feet; total length, 314 feet; face in hard porphyry. 1000 level.—We have cleaned and repaired for a distance of 14 feet the northeast drift which has been run from a point in our main north drift, 100 feet from our north boundary. This work is being carried on jointly by the Con. Virginia company and this company for the purpose of making connection with the Rule drift. This connection when made will afford a means of escape in case of accident in this part of the mine and give also a better ventilation. We have also done considerable repairing throughout the mine during the week.

Gould & Curry—200 level.—West crosscut started in northwest drift has been advanced 11 feet; total length, 872 feet; face in hard porphyry.

Hale & Norcross—1300 level.—We continue stoping out ore from the winze below this level and extracted during the week six cars of ore assaying \$29.35 per ton per car sample and 21 cars of ore at an average assay per car sample of \$21.65 per ton.

Alta.—During the past week we have made connection with the Lady Washington shaft. The drift is now in good condition and the ventilation perfect. We started an upraise this morning at a point 400 feet north of our south line and near the center of our ground. The material is soft quartz and yielding low assays. Nothing has been done in the winze since the 29th prox., owing to a flow of water from the north drift, which ran down and interfered with the work. In the meantime have started stoping above the drift on a small streak of ore which may lead to something better.

OREGON.

THE MAROTTA MINE.—*Baker City Democrat*: The Eastern Oregon Mining Company of Detroit, Mich., with Mr. John Thomas of this city manager, is making arrangements for extensive mining operations the coming season. The property of the company is the Marotte mine,

near Sparta. Last fall, Mr. Thomas went to Ruthburg, Idaho, and purchased for his company a ten-stamp mill from Mr. James Ruth and had the plant transplanted to the mill-site selected at the Marotte mine. There is also on the ground 60,000 feet of lumber for mill-building purposes, buildings, etc., and not later than March 1st next the erection of the mill will be commenced.

BONNET A MILL.—*Jacksonville Times*: The company interested in the Mountain Lion group of mines in the Missouri Flat district have purchased a five-stamp mill with concentrator, which will be shipped in a few days. The prospects for a paying property are very encouraging.

SOLD PLACER MINE.—Judge Fullerton and John Rast have sold the Steam Beer placer mines, located in Grave Creek district, to Elvin Nicodemus of Chicago, and the consideration was \$6000. These mines have been worked for several years past, under the management of Frank Oggier, and have yielded a good income, says the *Roseburg Review*. The property comprises about 160 acres of placer ground, adjoining the mines owned by the Taylor Company. The new owner has taken possession, and will work the mines on a much larger scale than heretofore.

UTAH.

TO THE EDITOR:—There is considerable excitement now, and has been for two months, at the mouth of Bingham canyon, over some very rich placers. Some four months ago George Leroy, an old miner and prospector, who has been in most of the mining camps in the West, came here, and, after looking around for a week or so, discovered rich placers at the mouth of Bingham canyon, where people had been traveling over for the past 30 years. The ground pays to the depth of 85 feet (no bedrock yet), and averages 80 cents per cubic yard. The gold is middling coarse, considerable being flaky. The bars are all good pay, and the hills will all pay on each side of the creek. Claims are all taken for miles down the creek. A company has been incorporated, composed of Salt Lake capitalists, under the name of the Jordan Valley Placer Mining Company. They have 480 acres, and are now bringing in a ditch five feet wide and two feet deep from Bingham creek. They are making preparations to commence hydraulic mining as soon as the snow begins to melt, and expect about 1000 inches for three months. They have also commenced an open cut and flume, five miles below, so as to be able to work both sides of the creek.

AUGUST JOHNSON.

Bingham Canyon, Jan. 16, 1894.

NEW MEXICO.

HUNTING FOR GOLD.—A dispatch from Albuquerque says: "Mining is active all over the Territory, and, since the low price of silver, rich gold strikes are being recorded in every camp almost daily. The Territory never has enjoyed a better mining boom than now. A few days ago C. T. Brown and others purchased the Queen of the Valley mine, in Water canyon, Socorro county, and the report reaches here that they struck a vein of free-milling ore that runs high in gold, and in consequence a number of locations have been made in the canyon. Great excitement prevails at Socorro over the strike. A short time ago a party of Albuquerquians located several mines near the Cochiti Indian village and commenced active work. They made several good strikes and attracted the attention of Col. T. B. Mills of Las Vegas, who visited the camp with J. T. Dongine, a pioneer miner of Nevada, and who represented that State in the Department of Mines and Mining at the World's Fair. After examining the ore and formation, Mr. Dongine stated that there was gold in any quantities in the district, and to-day word is received of a big strike in the North Star mine, the ore running at least \$3000 in gold to the ton. Wallace is the nearest railroad station, and advices from there state that a number of parties are outfitting to go to the camp. Captain Frank Pagaly and others of this city have extensions to the North Star, and they are enthusiastic over the reports."

IDAHO.

A \$65,000 MINING DEAL.—*Boise Statesman*: Dan Peonar has sold to the Trade Dollar Mining Company of Silver City his group of mines adjoining the company's property, comprising the Sierra Nevada, Standard and Colorado, the consideration being \$65,000. All the mines of the group are old-time properties. The Sierra Nevada and Standard are gold mines and the Colorado is a gold and silver mine. All the ledges are large and the ore assays well. It is estimated that at least \$300,000 has been taken from the Sierra Nevada alone. The ruins are nestled among a number of splendid properties. They are extensions of the Trade Dollar and Black Jack, the great value of which has already been established, while to the west are the Alpine and Little Chief.

TO START UP THE POORMAN MILL.—*Idaho Avalanche*, Jan. 27: Superintendent Shanks received a cablegram last week from Managing Director J. C. Kemp van Ee, to start the mill as early as practicable. We visited the property last Tuesday and found workmen busily engaged in carrying out the instructions. The two 6-foot Frue vanners received last fall were being placed in position and necessary changes made in the mill for the new machinery. An abundant supply of water is available for milling purposes, and ore hauling will be commenced soon. Within a week or ten days the welcome toot of the mill whistle will be heard. There are now some 300 tons of ore in the ore house at No. 3, considerable stored in unused crosscuts in the mine, and that on the Belle Peck dump. As soon as hauling commences, a force of miners will be put in the stopes. Timbers and supplies of every kind are now at the mine. The crosscut from the Belle Peck to the Oso is progressing steadily.

Electricity.

Transmission of Power.

The predictions of electrical experts as to the transmissibility of electric currents for lighting and power purposes have been received with the credence that the utterances of men who have accomplished things little short of the marvelous are entitled to, says the *Milwaukee Wisconsin*. But there is a difference between possibility and practicality, and unless it can be demonstrated that power can be carried to factories from dynamos at waterfalls more cheaply than it can be generated and applied with steam boilers and engines the calculations of those who have been figuring upon the utilization of the enormous amount of water power going to waste on unused streams will come to naught.

In a report from Chemnitz as to the result of experiments in the transmission of electrical currents from waterfalls in Switzerland Consul Monaghan shows that the cost of electrical power exceeds that of steam power. Steam power in Switzerland costs \$46.82 per horse power per annum for 50-horse power, \$29.61 for 300-horse power, and \$25.54 for 500-horse power. Electric power transmitted five kilometers, or 3.1068 miles in an air line, costs \$57.68 for 50-horse power, \$31.27 for 300-horse power, and \$24.48 for 500-horse power. This is a showing contrary to the calculations of people who have permitted their expectations to run wild.

Consul Monaghan says that Switzerland, with its freshets, its uncertain water supply and its electrical storms, is hardly the place for experiment in the transmission of electric power by wire from waterfalls, but the difficulties there encountered are likely to be met in varying degree wherever similar conditions exist.

The result of the experiments in Switzerland will be of value to electrical engineers in this country, who are measuring probable cost as they proceed. It is only the dabbles in the electrical science who can already see a network of wires running over the United States from centers of energy at waterfalls.

Operating Lock Gates Electrically.

The *Engineering Record* of November 18th has a communication, in which this system is proposed by Thomas Munro, M. Inst. C. E., superintendent of the Soulanges Canal in the Province of Quebec. Mr. Munro writes that an electric motor transmits power through a train of gears to a pinion which works into a rack placed on the side of a six-inch I beam. The end of this beam is attached to the top of a lock-gate, which it pushes shut or pulls open as may be required. The operation takes about 55 seconds, and is performed with perfect ease. It is proposed to operate two pairs of gates and four filling and emptying sluices from one point in the center of the lock and upon whichever side may appear advisable. The experiments are not yet completed, and Mr. Munro expects that the apparatus will be much simplified before being used on the canal.

Temperature by Photography.

The temperature of the blast furnaces at the Royal Mint is now recorded by means of photography. A thermo-electric pyrometer is employed, the shot of light from the mirror being received on a revolving drum covered with sensitive paper. The curves thus produced give a record of the variations in the temperature of blast, and by watching these curves, it is said that a greater regularity of work is obtained.

Metal from Pulp.

There has just been built in the factory of the W. S. Hill Electric Company, Boston, a piece of electrical apparatus which is both

novel and efficient. It was designed by Prof. Carmichael of the Massachusetts Institute of Technology, and perfected by W. S. Hill. The purpose for which this device has been built is by the use of magnets to extract every particle of metal from pulp which is used in the manufacture of paper, which has proven to be a great hindrance both in the manufacturing and using of papers.

Diamonds in Electric Arc.

M. Moison, a French electrician, who had been experimenting with diamonds in the electric arc, says: By starting the arc slowly and placing a diamond in the crater, it is brought to incandescence and increases in size, covering itself with a black mass formed entirely of graphite. When the diamond is placed in an electric furnace it breaks into small fragments, each of which is changed into graphite; the stable form of carbon at the temperature of the arc is therefore graphite. In an oxy-hydrogen lamp at a temperature of 2000 degrees, a diamond was covered with a black coating, but he never obtained any graphite.

Singular Origin of Fire.

A Connecticut paper mentions the peculiar origin of a fire which occurred recently in a dwelling house in Norwalk. An electric railway passes the place, and it appears that the return current, some of which escapes from the rails into the ground, followed an iron water pipe into the cellar of the house, then switched off to a gas pipe at a point where the two came in contact, and followed the latter to the meter, where it melted the lead connection and ignited the gas. The flames had caught the floor timbers when they were discovered, but the fire was extinguished with but trifling damage.

Electricity and Tricycles.

There was some talk here, says *Invention*, a little while ago of electrically propelled tricycles superseding the use of cars, and some such idea seems now to have reached Italy, where, it is reported, experiments are now being made with light electric vehicles somewhat larger than ordinary tricycles, the vehicle being equipped with a battery of ten cells, capable of yielding sufficient energy to propel them for from three to five hours. We shall be interested to learn the result of these experiments.

To Stop Runaways.

A scheme to prevent runaways is to have a small electric battery in the vehicle with wires running to the horses' nostrils. When the animal bolts a press of the button will stop him instantly. It is said to have never failed.

Trolley Accidents.

The Supreme Court of Massachusetts has rendered a decision making electric street railway companies liable for damages in the case of street travelers who are injured by the falling of overhead wires connected with the railway.

In a Cold Cycle.

That the continent of Europe is passing through a cold period has been pointed out by M. Flammarion, the French astronomer. Says the *Scientific American* concerning the matter: During the past six years the mean temperature of Paris has been about two degrees below the normal, and Great Britain, Belgium, Spain, Italy, Austria and Germany have also been growing cold. The change seems to have been in progress in France for a long time, the growth of the vine having been forced far southward since the 13th century, and a similar cooling has been observed as far away as Rio de Janeiro, where the annual temperature has been going down for some years past.

THE GRIFFIN MILL.

A perfect pulverizer of all refractory substances by either the wet or dry process. It works better and at less expense than any other Mill, and is conceded to be the only perfect pulverizing Mill Manufactured.

IMPROVED FACILITIES, FINEST WORK, THE LOWEST PRICES.

Perforated Sheet Metals, Steel, Russia Iron, American Planish, Zinc, Copper and Brass Screens for all uses.

MINING SCREENS A SPECIALTY.

221 & 223 First St., San Francisco.

Zinc, Copper or Brass Screens for all purposes. Cal. Hornia Perforating Screen Co., 145 & 147 Beale St., S. F.

The Best Mining District

On the Pacific Coast!

GRASS VALLEY, CAL.

THE BEST NEWSPAPER published in the district is

THE TIDINGS.

Daily and Weekly edition. Gives all the Mining News, Dealers in Mining Machinery and Mining Supplies will find THE TIDINGS the best medium for directly reaching the owners or managers of mines. Investors in mines will find it to their advantage to subscribe.

Many mines are in successful operation, and new enterprises are being instituted and many others are in contemplation.

DAILY, \$4.00 a year; WEEKLY, \$2.50, in advance.

H. S. SPAULDING, Publisher.

Market Reports.

The Markets.

SAN FRANCISCO, Feb. 8, 1894.

The London silver quotation of 29 1/2 pence to day was the lowest ever officially recorded. A sale was reported as low as 30d in June, 1893. The New York price yesterday was 64 1/2c, or 2 1/2c above the lowest on record, in June, 1893. That the latter market has not declined to the same extent as London is due to the fact of its not being so well stocked with silver. The heaviest losses have fallen on the London dealers, who had been accumulating bars at Indian ports in anticipation of an import duty.

Dun's Review of January 27th, commenting on the silver situation, says: All the markets for commercial bar silver were in a semi-demoralized condition, the range of prices for the week being very wide. The disturbance began on Saturday, when the news of the abandonment of the Indian import duty proposition was followed by the announcement that the Indian office in London would not maintain its minimum rate for sale of council bills at 15 1/2d the rupee, but would consider lower bids. For two days it was feared that the plan was to sell bills for whatever they would bring, and consequently there was little or no market for silver. On Wednesday tenders for 50 lakhs of rupees in Indian council drafts were invited, but the original bids of 15 1/2d @ 15 1/2d were declined. Later 25,000 were sold at 15 1/2d @ 15 1/2d @ 15 1/2d, and the silver market thereupon recovered a little on the theory that the worst was known. Purchases, however, were mostly speculative, and the temper of the market was bearish. The effect of the action of the Indian office will be to bring council bills into competition with silver in eastern settlements, with the probable results of depressing silver and stimulating India's export trade.

Mint Coinage for January.

The foreman of the coinage department of the United States branch Mint in this city reports the coinage for January as follows:

Descriptions.	Amount.
Double eagles.....	\$2,320,000
Half dollars.....	220,000
Quarter dollars.....	20,000
Total.....	\$2,560,000

The coinage for the first seven months of the fiscal year beginning July 1, 1893, as compared with the corresponding period of 1892, makes the following showing:

	1892-93.	1893-94.
Double eagles.....	\$12,860,000	\$12,323,500
Eagles.....	228,500	228,500
Half eagles.....	415,500	288,000
Standard dollars.....	700,000	700,000
Half dollars.....	198,720	590,000
Quarter dollars.....	110,000	248,200
Dimes.....	22,901	149,140

NEW YORK, Feb. 8.—Following are the closing prices for the week:

—In the legislature at Victoria, B. C., Tuesday, a resolution was adopted unanimously to have the duty modified on rubber goods, agricultural implements and machinery, mining appliances and other goods not manufactured in the province.

Mining Share Market.

SAN FRANCISCO, Feb. 8, 1894.

There has been some activity in the Comstock market during the week. The leading stocks of the north end, middle and Gold Hill, were in steady demand by the principal brokers in both boardrooms and most of the offerings appeared to come from short sellers. A large short interest is always beneficial to a strengthening market.

In the Comstock mines the prospecting work recently started is going ahead with vigor. Should there be improvement at any point more men will be added to the working forces.

Eleven miners have been added to Best & Belcher force of underground employes for the purpose of reopening the old north drift on the 1,000 level in connection with the Rule drift being advanced from the Consolidated Virginia shaft.

The following financial statements show the conditions of the different companies on February 1st, without the expenses for January having been paid:

	DR.	CR.
Bodie.....		\$6,942 05
Bulwer.....	\$4,004 18

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING JAN. 30, 1894.
513,629—CHECK FOR HORSES—W. C. H. Amundsen, San Diego, Cal.
513,749—TICKET HOLDER—F. D. Atherton, S. F.
513,475—FAUCET—M. L. Bergman, Spokane, Wash.
513,704—RAIMON-SHEDDER—S. B. Hies, Riverside, Cal.
518,900—WIRE TIGHTENER—W. B. Flaiding, San Jose, Cal.
513,910—STORAGE BATTERY—O. B. Fralery, S. F.
513,905—TRAP—Hubbard & Judkins, Los Angeles, Cal.
513,776—BLANK FREDER—Oray & Murch, S. F.
513,778—WIRE-STRUTTER—J. H. Gregory, Ione, Cal.
513,923—EXHAUST NOZZLE—E. W. Harris, Palmdale, Nev.
513,909—SPONGE WORKING MACHINE—S. Heron, Los Angeles, Cal.
513,780—HOP TRAILER—E. C. Horst, Sacramento, Cal.
513,930—WAVE POWER—Husted & Doolittle, Los Angeles, Cal.
513,790—CIRCUIT CLOSER—H. Lewis, Carson, Nev.
513,715—GATE—B. O. McCoy, Sulphur, Cal.
513,811—FLOW-SHAFTER—S. S. Morrill, Stockton, Cal.
513,690—SPRING GUN—W. B. Morris, Seattle, Wash.
513,813—SHINING-BINDER—Munro, Hart & Baty, Sedro, Wash.
513,718—BATHING BRUSH—F. Neidl, S. F.
513,694—WRENCH—W. A. Papou, Baker City, Or.
513,634—TELEPHONE SIGNAL—Sahlin & Hampton, S. F.
513,737—POWER—E. A. Starks, S. F.
513,849—CONCENTRATOR—G. W. Walt, S. F.
23,019—SPONGE DESIGN—A. Kaiser, Stockton, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast Inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

SMOKELESS POWDER.—E. A. Starke, San Francisco, Cal. Assignor to the U. S. Smokeless Powder Co. No. 513,737. Dated Jan. 30, 1894. This invention relates to an improved explosive compound which is especially designed for use in guns and other weapons in which it is desirable to produce the maximum effect without the production of large quantities of smoke and fumes. It consists of an improved compound of materials which will produce this result.

BATHING OR FLESH BRUSH.—Frank Neidl, San Francisco, Cal. Assignor to P. H. & F. Buchanan. No. 513,718. Dated Jan. 30, 1894. The object of this invention is to provide a brush with attachments by which the brush may be raised, lowered and otherwise adjusted so as to be applied to the surface of the body at different parts, and to so construct and arrange the brush that water may be applied, and

in conjunction therewith an electrical current which may be applied either with or without the use of water. This device may be used as an attachment to a bath tub, shower, or other suitable or convenient appliance for bathing purposes.

STORAGE BATTERY.—George B. Fralery, San Francisco, Cal. Assignor to John L. Eckley. No. 513,910. Dated Jan. 30, 1894. In the ordinary construction of storage batteries, the substance which serves for the storage of electrical energy is contained in open spaces made in flat leaden plates which are afterward secured together in series. It is difficult to retain the filling in the spaces in these flat plates and if the battery be overcharged, the plates will be hooked and twisted out of shape. The object of this invention is to provide an improvement in this class of batteries which will render the elements capable of retaining the filling material in place, and of resisting any tendency to buckle or warp out of shape. It consists of a series of concentric cylindrical perforated tubular elements with an active filling material placed within and between the elements and a means for exciting the same.

BLANK FEEDING DEVICE.—J. A. Gray and J. H. Murch. Assignors to Robert D. Home, Gold Beach, Or. No. 513,776. Dated Jan. 30, 1894. This invention relates to an apparatus for feeding blanks or pieces of any description, such as metallic disks, can heads, sheets of metal which are to be used for making cans, or cylindrical or globular objects, or for other purposes where the pieces are to be fed in succession singly. It consists of a lifter to which each article adheres, and a carrier to which the lifter is attached, mechanism by which the lifter is first depressed upon the article so that the article is caused to adhere to it, and means for lifting the carrier and the adhering article, and transferring them laterally to a point where the article is to be deposited, and in conjunction with this a means for disengaging the article when it arrives at the point where it is to be deposited or used.

Very Important to Gold Miners.

The exhibit at the Midwinter Fair of silver plated copper mining plates, for saving gold in quartz and placer mining, made by E. G. Dennison, proprietor of the San Francisco Plating Works, 653 and 655 Mission street, in this city, is the finest and most extensive exhibit ever made of gold-saving amalgam plates. Two of the plates are the largest ever made, 66" by 20", containing 55 square feet each; six other mining plates, 60" by 96", 40 square feet each, and several 48" by 96" plates, 32 square feet each, are included, making in all over 400 square feet of surface.

The silver plated plates in the three gold quartz mills of the Huntington, Risdon and Hendy exhibits were also furnished by Mr. Dennison, who is the pioneer manufacturer of these goods.

The Dennison silver plated mining plates are known as the best and are in use wherever there is gold mining.

Metal goods of every description are plated at his works, with gold, silver, nickel, brass, copper, etc. Twenty-five medals have been awarded to him for best gold, silver, nickel, etc., plating, and for the best silver plated mining plates.

Mr. Dennison has four separate exhibits in the Mechanical Arts building, and one in the Quartz Mill building, erected by the State Mining Association.

Assessment Notices.

GOULD & CURRY SILVER MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Virginia, Storey County, Nevada.

Notice is hereby given that at a meeting of the Board of Trustees, held on the 31st day of January, 1894, an assessment (No. 73) of Fifteen (15) Cents per share was levied upon the capital stock of this corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the 8th day of March, 1894, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on THURSDAY, the 29th day of March, 1894, to pay this delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Trustees.

Office—Room 89, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

Coast Industrial Notes.

—The quarrymen of Spokane, Wash., have formed a trust to secure better prices for their stone.

—The steamship Miowera was closely inspected at Esquimalt Tuesday morning, and it was found that 140 plates on her bottom will be ultimately necessary.

—Vallejo had bonfires, gun salutes, music, fireworks and bell-ringing Saturday night last. The completion of the water-works was the occasion of the noisy demonstration.

—The citizens of Oakland and Berkeley will not subscribe \$225,000 to the capital stock of the Oakland Terminal Company (opposition ferry). The whole scheme to raise the money is at an end, and F. M. Smith, who made the proposition to the citizens, has called in all his promises.

—The old and reputable commission firm of Scotchler & Gibbs has assigned for the benefit of creditors, with liabilities exceeding \$200,000, and by some estimated to approach \$250,000. This is one of the heaviest failures that the commercial world in San Francisco has known for a long time, and the high standing and reputation for prudence of the firm make the assignment more noticeable.

—A dispatch from New York says that the limit within which stock could be deposited in favor of the scheme of the reorganization committee of the Nicaragua Canal Construction Company has expired. Nearly 100,000 shares—considerably more than a majority—have been handed in, consequently the reorganization agreement becomes operative and goes into full effect.

—The formal transfer of Sacramento's immense street-car system took place February

ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Dumbility and Effectiveness, combining both Side and End Motion with a Bumping Belt. SPEED AND INCLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION. CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE (at present).....\$350 EACH,
 Including Prepared Canvas Belt.

FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ores difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ore. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 9 1/2 per cent; from East ledge, * * * a saving of 92 per cent.

The concentrator runs very easy and requires but slight attention. One man attends to rock-breaker, crusher and concentrator. You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,

E. L. BALLOU, Propr. Ballou Reduction Works.

MINE BELL SIGNALS

ADOPTED, USED AND IN FORCE IN ACCORDANCE WITH STATE LAW.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12x36 INCHES, THE MINE BELL SIGNALS AND RULES provided for in the Voorhes Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to Be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth, so as to withstand dampness, for 50 cents a copy.

An Ocean Beach Mine.

A beach-sand mine of large dimensions is being worked at Gold Bluff, Humboldt county, and is said to be yielding to its owners very large profits. The surf of the ocean is a most important factor in the development of the property, for the reason that it is instrumental in renewing the auriferous sand, and carries away the gravel of the great bluff which terminates the beach. The sand is really the concentrates from the great gravel deposit which at this point forms the bluff. The deposit is evidently an ancient river channel that at one time probably formed the outlet of the Klamath river to the ocean. It presents a cross-section surface to the ocean of about six miles, and extends to eastward about eight miles. It has been prospected to a depth of 500 feet, but bedrock has not been reached. The gravel is clean and white, with small pebbles and no boulders. The gold is fine, but clear and easily recovered.

The method of working is unique. At the point where the sand is secured there is a sort of inlet from the ocean, a lagoon being formed behind the ocean beach. Between the two peninsulas of the lagoon which form part of its western boundaries is a bar which is constantly acted upon by the surf; and it is from this bar that the auriferous sand is taken. The sand is packed very solid. It is raised by means of an endless chain and buckets to a height where it can be handled, and is then amalgamated.

Mr. R. K. Chapman, now in this city, was for many years owner of the deposit. He says that he frequently secured \$1,000 per day from the sand. It will average from \$12 to \$15 in gold per ton. He sold out to Mr. Coffin, and associates, about a year ago. It is Mr. Chapman's opinion that the gravel will eventually be worked by the hydraulic process. It will be necessary, however, to bring water a distance of nearly fifty miles, and the cost will be very heavy. It can be made, he said, the most gigantic hydraulic mine in the world, for the deposit

IN THE SIERRA NEVADAS—LAKE SPAULDING.

is inexhaustible and the gold will average about 15 cents per cubic yard. The debris could easily be deposited in the ocean, where it would be carried off by the tides. In Mr. Chapman's opinion the gravel will undoubtedly be worked in this manner. Mr. Coffin's holdings aggregate about 2,000 acres.

TROUBLE is said to have arisen between James G. Rule

and the management of the Consolidated California and Virginia mine, relative to the terms of the contract by which he was to uncover an ore body on the 1100-foot level. The management, it is alleged, have greatly hampered Mr. Rule in his operations. They have refused to allow his personal expenses, or the selection of men under him. Besides all this, Mr. Rule has been much interfered with by illness. It must be admitted that unprejudiced mining men never had a great deal of confidence in Mr. Rule's ability to find a valuable deposit. Some persons are mean enough to say that the whole contract is simply another device to bull stocks. If so, it was certainly successful, for Consolidated California and Virginia went in a short time from \$1.25 to \$5.

A NEW REGULATION has been promulgated by the Southern Pacific Company in regard to the transportation of high explosives. The company will hereafter decline to carry black ignition powder, wood powder, dynamite, high explosive caps, or other high explosives of whatsoever kind or designation, unless the company is exempted from all damage to such freight; and further, that the company shall be indemnified against any loss or damage to person or property arising from the combustible or explosive character of said freight.

In the Sierra Nevada.

The two views on this page are a continuation of the series in last week's issue of the PRESS. They are types of the mountain scenery of the Sierra Nevada; and, besides, Lake Spaulding bears a very important relation to mining operations in Nevada and Placer counties. Besides being in itself an immense reservoir, it is a collecting basin for all the lakes above. The dam, shown last week, is a fine piece of engineering. Not one ounce of cement was used in its construction. It was built under the direction of John Spaulding, superintendent of the South Yuba Water Company.

TABLE OF CONTENTS.

ILLUSTRATIONS.—California Midwinter Exposition—Partial View of Buildings and Grand Court During the Parade on Opening Day, 103.
 In the Sierra Nevada—Lake Spaulding; Road to Bear Valley, 97.
 EDITORIALS.—Opening Day at the Fair, 103. An Ocean Beach Mine; In the Sierra Nevada; Miscellaneous, 97. No Jobbing of California Mines; Why Silver is Down; Outlook for an Appropriation; Miscellaneous, 98. The Trans-Mississippi Congress; To Hydraulic on a Large Scale; Miscellaneous, 99.
 CORRESPONDENCE.—Surface and Deep Mining, 99. Mountain Mines—Tulame County; The Proposed Mining Law, 100.
 MISCELLANEOUS.—Chlorination of Gold Ores in California; Making Gas from Coal Oil; Metalliferous Mining in California, 101. Hydraulic Mining, 102. The Regulation of Foreign Petroleum Supply; Electricity in Mining in France, 103. Marble Deposits of California; The Situation in South Africa; Mines for Idle Men; Temperature of a Coal Bore, 104. Slickens; Foundry Notes, 99. Patents, 110. Industrial Notes, 111.
 SCIENTIFIC PROGRESS.—Science of Weather; The Ideal Source of Light; Phosphorescence of Paper; Vegetable Photography; Electricity With Gatling Gun, 105.
 MECHANICAL PROGRESS.—Production of Colors in Glass; Aluminum Boron Bronze; Smoke-Preventing Laws; Process for Coking Dry Coals; Two Novel Locomotives; To Extract Gutta-Percha; Novel Fire Engine, 106.
 USEFUL INFORMATION.—Effects of Trees on Climate; Telephone Patent Expires; Ventilation; Keeping Warm; Whalebone from Hair, 108.
 ELECTRICAL.—Electric Vibration Regulated; Effect of Electricity on Steam; Ingenious Surgical Device; Oil and Electricity, 103.
 MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 109.
 THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 111.

The Treasury Department at Washington announces that the gold output for 1893 in the United States reached \$37,000,000, an increase over 1892 of \$4,000,000. In Colorado the output has increased from \$3,000,000 in 1892 to \$5,000,000 in 1893, while the gains in other gold-producing sections are unusually large.

MR. HENRY K. B. DAVIS, of Philadelphia, is the owner of a patent on a process for rapid chlorination of ores under pressure, also for rapid filtering of the pulp; in the former, he mixes the ore with his chlorine preparation and tightly closes the cask, and as the material generates the chlorine gas, it at the same time makes its own pressure. His patent for filtration is that of filtering through charcoal, the same time converting the gold from a chloride to a metallic and precipitating the same in the charcoal filter.

ONE or two Grass Valley papers complain that the patent system of ownership of mining claims is working real injury to the interests of Nevada county, inasmuch as the owners of prospects refuse to work them themselves and will not sell for less than a sum that is practically prohibitive. There are no doubt many cases where actual benefit would result if an owner did not have quite so secure a hold upon his idle property. But every man has a right to do what he will with his own. When he cannot, government ceases, and anarchy results. If it is not possible to obtain absolute title to mining ground, the industry would be destroyed, or, at best, it would be terribly crippled. Mossbacks afflict every country, Nevada among the rest. They never die. They are the brakes on the wheels of progress, and are useful in preventing runaways, even though they do sometimes stop the train.

VIOLATION of the mining laws has buried 13 men 600 feet under ground in the Gaylor mine at Plymouth, Pa. If they are alive they cannot be rescued for several days, but experienced men who have made a careful survey believe there is hardly one chance in a hundred that they still live. In mining coal in the vein, massive pillars of coal are left standing to support the roof, forming a natural colonnade along the main gangways and planes. When the vein begins to fail and good coal in that part of the mine is hard to get then the robbing of pillars commences. The mines do not generally cave in without a peculiar warning, which is well known to the men when working under ground. There are strange noises caused by the earth settling, and sometimes for days before the final fall pieces of coal and rock will drop from the ceilings and sides of the gangways. This is called "chipping" and indicates that a greater fall is coming, and the mine is said to be "working." This was the condition of the Gaylor mine for several days before the disaster.

No Jobbing of California Mines.

There is one feature of California gold mining which is in the highest degree creditable to the industry and to the men who are its chief promoters; and that is the almost total absence of stock jobbing and stock manipulation in connection with the mines. It is a fact that very few California mines are listed on the stock boards and that operations thereon are confined largely to the Comstock. It will be remembered that an effort was made last year to secure listing of California properties at the exchanges, and all charges to the mining companies were waived; but it ended in almost total failure. There are few or no fake companies in California, designed primarily to mine the pockets of the stockholders. Instances of fraud are becoming more infrequent year by year, until now, it is safe to say, illegitimate concerns are as rare in California gold mining as in any other industry.

The great curse of Colorado mining is the stock methods which prevail in all classes of mining. The universal method is to form a company and make its stock subject to public sale. In former years a common method of influencing the value of shares was to declare dividends which were never earned. No statement of assets and liabilities, receipts or expenditures is required by law to be published. A few years ago in Colorado an attempt was made to have an act passed compelling mining companies to make at least annual statements of their receipts and expenditures. The stockholders and all interested in mining stock companies were immediately arrayed against it. "It will ruin our business," said more than one. "It will stop mining stock company fakes," was the reply. "We are not guardians for the fools," came back the rejoinder from a member of the Legislature. "This fake dividend paying is no more than the railway and other great corporations do," openly declared one promoter, "and nobody says the great railway kings are frauds." So the bill was lost, and Colorado continues to be the asylum of mining frauds.

If one were to form his judgment of the dimensions of Colorado stock operations by the holdness of the headlines and size of the exclamation points in the Denver papers, it would be that the boards are a daily scene of intense activity and excitement. One day recently the daily transactions were advertised under the headlines, "Advance in Stocks," "Great Amount of Sales," "Total Amount of Transactions for the Day, 14,000 Shares." The total sales for the day realized, less one sale, \$308.25. The exception was a heavy sale of 500 shares at \$2.15, bringing the total up to \$1383.25.

These things do the industry no good. It is not possible by such methods to convince really heavy capitalists that there is a great movement in stocks, and that now is the time to invest. We are bound to say also that the statements of enormously rich strikes in various districts now being sent out so industriously and so indiscriminately are not calculated to invite entire confidence in these fields. No man of experience in mining will accept them as true. They are absurd, and sound childish to old California miners. The effect will certainly in the end be to injure the very industry they are intended to benefit. It ought not to be so, for Colorado has gold fields of real merit. Several of the districts are already producers, and if the right methods are pursued, and if capital is not frightened away by such meretricious advertisements, others will secure the attention their merits deserve. But no permanent development can be assured if mining operations are made incidental to stock jobbing. The industry will have no genuine foundation, and it will fail.

It may be added, in this connection, that the manipulation of South African shares in the London market has become a very great evil, and threatens to do immense harm to the Johannesburg fields. The London *Mining World* recently contained an article severely attacking the methods in vogue. Says the *Mining World*:

As these mines are at present managed, the investor takes his chance in a big gamble, in which the actual merits of the properties scarcely count as factors. The best of the mines are manipulated by the big financial houses, and they do with them what they will. The investor, therefore, who sees the wonderful returns month by month should not base his calculations upon these, but upon the probable course that operators may take. When he invests his money and sees anything like a decent profit, he is very foolish not to take it, and to be satisfied with it, even should the "rig" be carried to a higher point than he anticipated. The chances are the "operators" might have got out before his profit was secured, and then, like Mr. Mantalini, they would have "grinned at him dembly." It is a great pity that an important industry like that on the Rand should thus be controlled by a comparatively small group of people, but it is no use blinking facts, and we intend to be plain-speaking about them.

THE tariff bill is to be reported to the Senate from committee next Tuesday. The general belief is that coal will hear a duty. There will probably be no change in the metals.

Why Silver is Down.

The heavy depreciation in value of the silver coinage of the world is certain to arouse the various nations to the necessity of its rehabilitation. The actual value of the silver dollar (judged by present New York prices) is less than fifty cents, and similar conditions prevail elsewhere. The general distrust in which silver is held is evidenced by the barriers raised against its international circulation. That is to say, a Canadian silver half dollar is not accepted at par in this country because its intrinsic value (expressed in gold) is not at par. An American half dollar is likewise discredited in Canada, but it passes at par in this country because the faith of the government is behind it. The government accepts the half dollar at par, and it is likewise accepted by individuals. It is true that England likewise guarantees its own silver circulation, up to a certain point; but England is a foreign country and its guaranty is not accepted in this country with the confidence held in our own government. In a more marked degree the distinctions between the several national coinages of silver are shown in South America. The nations in that part of the continent will not accept American silver. In Chile, for instance, the American half dollar is universally rejected. Why? Because this country is on a gold basis, and the dollar, expressed in terms of gold, is worth only half what it pretends to be.

The remedy is not necessarily a silver basis. Free coinage will settle the question so far as this country's coinage and its domestic circulation are concerned. But the international differences must be adjusted by international bimetalism. It is not too much to say that the countries of Europe see the necessity much clearer than when the conference at Brussels met. The depreciation in silver values lies as much as anything else in the fact that values are expressed in gold, and in the lack of confidence by each nation in the others' silver coinage; and the want of confidence arises largely from the fluctuations in the values of the two metals, making it impossible to tell one day what the exact relations of the metals will be the next. As long as values are unsettled, an interchange of moneys on a certain basis is impossible.

A previous agreement will change all this. An understanding that each nation will accept the moneys of the other at a rate previously agreed upon will remove the distrust of silver, restore it to its rightful position, and settle the monetary question. There are ample evidences that the nations of Europe are beginning to understand the situation.

Outlook for an Appropriation.

According to advices from Washington, California and other Pacific States that are in need of additional appropriations for waterway improvements are pretty certain to be disappointed in their expectations as to what this Congress will do in the way of making more money available for the needs of these States. Pacific Coast States, however, will not suffer much more than those in other sections of the Union. It is scarcely believed now that when the River and Harbor bill is reported to the House, and this report will be made within a few days, that there will be any provision for new projects in connection with waterway improvements. This assertion is based upon the fact that the total appropriation in the bill that will be reported will not exceed \$10,000,000, and may fall as low as \$8,000,000. Of course, the continuous improvements which previous Congresses have provided for will be continued. On account of the financial stringency it is necessary for this Government to cut all appropriation bills.

In view of these things the prospect for an appropriation for restraining dams in the Sacramento tributaries would seem to be dubious. It is certain that nothing will be obtained unless Congress is especially urged to make the appropriation; and it is likewise certain that the special needs of the State in this respect will not be adequately set forth, if no delegation, charged with the duty of informing Congress on the subject, is sent on to Washington. The great importance which California attaches to the matter is well attested by the conditional appropriation of \$250,000, already made by the State Legislature, for the construction of dams; and the willingness of the State to undertake the work in conjunction with the Government ought to be duly and properly emphasized. The time is already getting late, and it will be possible now only to get an amendment to the measure after it is reported to the House. There is no hope for a special bill. Something should be done at once.

THE ample rains and mountain snows of this year give assurance of abundant water, and the hydraulic miners along the Scott, Salmon and Klamath rivers are sure they will take out more gold than ever before. The season will last until late in the fall.

Surface and Deep Mining.

By Taylor D. McLeod.

In the otherwise excellent and pertinent letter of Mr. W. S. Chapman, in the last issue of the PRESS, entitled "Needed Changes in Mining Methods," occurs this remarkable statement: "The first thing to do is to sink a shaft, deep enough to prospect the mine thoroughly, so as to know whether you really have a mine or not. The shaft should be sunk, ordinarily, to 1000 or 1500 feet, levels opened at each 100-foot station, the veins crosscut at each level, and when that work has been done, the miner will know whether he wants a 20-stamp mill, a 40-stamp mill, or a 100-stamp mill, or any mill at all."

Not considering the utter impossibility of any set of poor men—miners—accomplishing a work of any such magnitude, this very erroneous opinion expressed in the columns of a journal of the standing and circulation of the MINING AND SCIENTIFIC PRESS, and permitted to pass uncontradicted, will certainly redound to the injury of mining prospects, i. e., undeveloped mines in a nascent condition.

At the first glance the inquiring capitalist, when confronted with a preliminary expenditure approximating \$50,000, to simply "prospect" and prove the value of a mineral vein, would unhesitatingly prefer to invest his surplus coin in the culture of rutabagas, or the manufacture of cheese from the Milky Way. I fully concur with Mr. Chapman in his condemnation of first building a mill and then hunting for a mine. Our hillsides and gulches are dotted with these monuments of too sanguine hopes, upon which "failure" may be written as an epitaph. Yet, if it required a 1000-foot shaft to find ore justifying the purchase of a stamp-mill plant, it is very doubtful if the music of a single run of stamps would be heard throughout the land. Of course, if there is a known ore chute, of value, demonstrated and dipping toward an adjoining claim, that probably might be tapped by sinking a 1000-foot shaft, it might be thought advisable to drive through a semi-barren zone for that purpose. But these are exceptions.

Again, it is a fallacy for one to pin his faith on the belief that "ore increases in value with depth." The vein may widen, and very often does, and the ore in a few instances becomes richer, but it is the exception that proves the rule. The character of the ore will change below the zone of oxidation and is found less "free."

The Bulk of Gold Near Surface.—It is safe to assume that 80 per cent of the value of the gold quartz mines (and they are the mines referred to, I believe), has come from and is being mined above the 500-foot level. Instances might be cited by the score. One or two illustrations will suffice. One is the Harqua Hala, Yuma county, Arizona, which, by the way, was twice, in its early stages, reported on adversely by California experts. Within four years of active life this mine returned an approximate output of \$1,500,000 in gold. It was sold, a few months since, for \$1,250,000, and this before reaching a depth of 500 feet. Again, the Vulture mine, same locality, thirty miles distant, with a record of \$20,000,000 output above the 600 level. California can furnish examples *ad infinitum*.

It is of prospects we are dealing, and a "prospect" premises a prospective, hence, suppositious value. To open a prospect aright requires a special and peculiar training. Each proposition must be considered individually and the plan of attack carefully determined, for misapplied development injures the property and is a costly experiment. There are then no assets; you cannot claim as realty a hole in the ground. And right here is where the danger lies: in the preliminary steps, the inception of the enterprise. Bucking against rock is slow and costly work at best. We must to the uttermost eliminate the element of chance. This is the province of the specialist in that line of mining.

How to Start to Work.—The ledge should be thoroughly pick prospected, after the topography and general physical condition of the immediate locality is understood. This is followed by shallow pits, shafts or open cuts crosscutting the vein at the most favorable mineralized points exposed. Careful tests and assays follow. This having determined the apex of the ore chute, then shaft sinking is in order, and drifts and crosscuts 70 to 100 feet apart to determine extent of ore chute, chimney or chamber.

Don't monkey with vertical shafting through the country rock or tunnel—unless there is an opportunity to drive an adit tunnel with the ledge. On prospect work, *find your ore and stay with it*. Later on, "working shafts" or tunnels can be run to facilitate cheap extraction. In preliminary open-cut crosscutting, if the ledge is wide it should be opened by a series of benches. An excellent way to secure check samples is to drive drill holes across the vein strata—a hole near each corner of and at foot of face of bench—carefully saving each six inches or foot of drillings, or the entire pulp if a general average is wanted,

for test or assay. Six to ten-foot drills should be driven into doubtful ground, or tapping the ground occasionally. The drillings kept for assay will save many a dollar in general mining, for there is more judicious economy required and possible in running a mine than in any other of the so-called legitimate enterprises. The curse of mining has been, and is, for that matter, not in the mines, but in the incompetent management, and that greater incubus, the "office mining." Take a given amount of money secured for development and working of a mine, fully one-half goes to keeping up the dignity of "the office" and its contingent ornamental constituency.

In conclusion, mines, like any other embryotic realty or property, are made, not found, and it takes money to do this. But a few years since "Nob Hill" was shifting sand dunes of little value. Money made it one of the most elegant and sightly localities of this country.

The judicious expenditure of a moderate amount of capital will make, almost surely, a good mining prospect where the conditions are found favorable. It is not a thing of value alone, but a producer of values. Hence, if a gold mining prospect does not show pay ore blocked out, on dump and "in place," to pay for all expenditures of development and cost of a stamp mill or other reducing plant, at the 500-foot level, it should be abandoned. Two hundred feet should "prove" the mine.

The reader should not infer from the above that the writer deprecates deep mining. On the contrary, deep mining is the most lasting and profitable of any class of enterprises. I wish to convey the fact that it does not require a vast expenditure of money to put a gold mine on a dividend-paying basis.

The aim and efforts of the actual practical miner are to put his mine on a self-supporting footing at the earliest possible moment, and, with the proceeds of the mine, purchase the more expensive machinery required in deep mining. The higher cost attendant on handling ore and water, timbering, etc., at the lower levels, to be met by the sinking fund (no pun) should be derived from the more shallow workings. It is a straight-away business proposition—make the mine pay for its own improvements toward the greater permanency assured in deep mining.

TAYLOR D. McLEOD.

San Francisco, Feb. 14, 1894.

Sliokens.

JAMES G. RULE intends to make another trip to the Comstock during the latter part of this week.

THREE THOUSAND river coal miners at Pittsburgh are on a strike against a reduction of half a cent per bushel in pay.

W. M. WATKINS, who was at one time superintendent of mines in Nevada, has died at Silver Cliff, Colo., of heart failure.

THE Plumas Eureka mine paid \$52,734 in dividends for the year 1893.

THE Arizona mining interests of C. W. Leach of Tombstone, who recently died of gas asphyxiation at Grass Valley, were worth over \$100,000.

THE Bunker Hill and Sullivan, at Wardner, is working one shift; the Frisco, at Gem, is working one shift, and the Granite has closed down entirely.

FRANK JURENS, who recently robbed the chlorination vats of the Alaska-Treadwell mine, Douglas Island, of \$10,000 worth of precipitates, has been arrested at Juneau.

CONGRESSMAN CAMINETTI denies that he is opposed to the improvement of Oakland harbor and Petaluma creek. He is simply opposed to their improvement under the continuous contract system.

GOV. JOHN E. RICKARDS of Montana is an ardent champion of silver. He believes that the white metal will be restored to an equal place with gold in the coinage of the country, and that in the next Presidential struggle the Republican party will champion free coinage.

THE Mammoth Mining and Milling Company has been incorporated. Principal place of business, Madera, Madera county. Capital stock, \$1,000,000, with D. M. Tomlin, C. G. Parsons, Robert L. Hargrave, H. J. Tomlin and B. W. Child of Madera as directors.

THE Tacoma smelter's output for January was 3200 bars of bullion, weighing 333,239 pounds, and valued at \$69,144.43. There were 2067.59 ounces of gold, valued at \$42,737.08; 23,693.31 ounces of silver, valued at \$16,065.42; and 331,472 pounds of lead, worth \$10,341.93.

A BEAUTIFUL piece of gold weighing \$41.90 was found by some rockers in the tailings in Nugget gulch, near Murray, Idaho, on Saturday last. It was flat, with one of the sides partially turned up. Not a speck of quartz was in it. The tailings are yielding almost as much as the original gravel.

THE Mercur mine of Utah has been sold to a syndicate, headed by Colonel Wolcott, of Colorado, for \$1,000,000. This mine has been paying dividends off and on for some time. The Mercur mine and mill have been frequently alluded to in this paper. Cyanide is in successful operation at the mill.

TELEGRAPH advices from Phoenix, Arizona, say that the Bob Groom group of mines in Whipsaw gulch, 30 miles north of Phoenix, has been purchased by W. M. Wilson, representing San Francisco capital. The price paid was \$100,000. The property is considered very valuable and is well developed.

THE Virginia Enterprise says: "The work of reopening the Central tunnel, to prospect the ground in the west part of the Ophir, is progressing at the rate of 100 feet a week. The tunnel has a total length of 900 feet, and the work now in progress is to make a connection with the Mexican shaft to secure an

air supply. When the tunnel is reopened its full length exploratory work of unusual interest will follow, as it is among the probabilities that even a more important discovery than the 'Rowe find' may be developed, as that vicinity is noted for gold-bearing quartz stringers, which, if followed, may result in the uncovering of an important ore body."

THE Poorman mine, at Burke, although closed down, is giving employment to 55 men. They are repairing the shaft, making the raise, putting in the compressor plant and overhauling the machinery in the concentrator. The bed for the compressor is completed and a building is being erected over it.

J. V. KEELEY, of the Yellow Pine mining district, Nev., is in the city. He says the recently discovered Keystone mine is working a ten-stamp mill and turning out \$30,000 a month. The average pulp value of the ore, he says, is about \$100 a ton. The railroad which is being projected from Goff will, it is thought, do great things for the district.

IN spite of the great depression of silver and lead, many of the mines of Aspen, Colo., are able to work at a profit. Such properties as are now working without loss are, with few exceptions, those which have the advantages of tunnel facilities in their upper, and electric machinery in their lower workings, reducing the cost of getting ore and waste to the surface to a minimum.

THE Mammoth mine, in Arizona, is about to resume operations after a suspension of six months. The local importance of the resumption of work with a full force is apparent when it is stated that the company distributes \$12,000 to \$16,000 per month for labor and supplies, 75 per cent of which circulates in Tucson. The mine will be running in full blast in a few days.

ARTICLES of incorporation of the Golden Cheriot Mine and Milling Company have been filed with the Alameda County Clerk. The capital stock is \$100,000, divided into 100,000 shares of the par value of \$1 each. The subscribers for stock are: A. F. Trenchel, 33,183; W. W. Moody, 100; William F. Hendsch, 16,666; Fred H. Ferr, 100; L. T. Farr, 33,183; Julius J. Hendsch, 16,667; O. E. Ferrigo, 100.

H. J. GOETHE, A. Meister, M. Miller, Thomas Rudick, Emil Heinrich, R. J. Gordon and Charles Schmidt have organized a company called the Pleasant Ridge Ditch Company, for the purpose of constructing and operating ditch properties, and to acquire, use and sell water and water rights. The gentlemen organizing the above company are interested in the Live Oak mine at Pleasant Ridge, Nevada county.

JAMES CHRISTIE, a prospector and miner, has recently returned to this city from a trip through New Mexico. He thinks that to be a very promising country in a mining point of view, and says that in Lincoln county, 12 miles from White Oaks, there is a vein of iron ore averaging 64 per cent of iron. The vein is 600 feet long and 24 feet thick. Within 15 miles of this iron, there is a vein of coal eight feet thick. Picarilla is the name of this promising locality.

THE House Committee on Public Lands has voted to favorably report the bill of Hartman of Montana for determining the title to mineral lands in Montana and Idaho within the limits of the land grants to the Northern Pacific Railroad. Under the bill, commissioners to be appointed by the President are to examine and classify as soon as possible all lands within these grants with regard to their mineral character. They are to reject all claims on behalf of the Northern Pacific on mineral lands, exclusive of coal and iron property. The action of the commissioners is to be final.

ARISING from the ashes of the Bullionville fire of last July, says the *Pioche Record*, comes the Phoenix Reduction Company, organized recently by W. S. Godhe and others under the laws of Nevada, and which promises much to its incorporators in the immediate future. Its property consists of the tailings there, some 75,000 tons or more, and the new mill just set in operation. One of the main features of the business will be to reduce Ferguson and other ores, and the company expects to be in a position to do this in a very short time.

A suit has been filed in the Superior Court that bids fair to rival the sensational developments in the notorious Hele & Norcross expose. It is entitled the Alta Mining Company vs. Monroe Thompson, R. N. Graves, L. Osborn, I. E. Jacobus, George H. Pippy, W. S. Wood, Chanceller Derby, E. Miller, E. D. Boyle, Charles Derby, Thomas Fitzsimmons, S. G. Whitney, I. P. Martin, I. W. F. Peat, the American Mill and Mining Company and Louise Arner Boyd. The complaint charges the late Seth Cook with having been at the head of a conspiracy of directors to control the mine for their own private ends. Bold assertions are made that "the conspirators" stole the stockholders' money right and left. An outline of the charges was contained in the Press of January 13th.

VERY often, says the *Denver Mining Industry*, we read in the newspapers published in the older mining towns, that Mr. So and So—John Doe or some other man—who has been off to other mining regions, seeking fresh fields and pastures new, has returned to "his first love," and declares that it is the best region he has seen. The fact of such an announcement is an illustration of a mining business truth worth considering. This truth is, that familiar and close acquaintance with a mining district is necessary to most men to actually know its merits. Incidentally it bears evidence that there are striking differences in mines and the methods of ore occurrence in different regions, each of which may be equally good, and that a man who knows one well, and has all his hearings there, may be at sea in another, and have a poor opinion of it, even though it may have equal or greater merit than the one he is best acquainted with.

Foundry Notes.

THE Fulton Engineering and Shipbuilding Works are building six 34-foot sectional Huntington mills for a mining company near the city of Mexico. A machine-shop outfit goes also with the plant.

THE Harqua Hala Mining Company, Ariz., is having constructed at the Union Iron Works a ten-stamp outfit, to be added to their 20-stamp mill.

THE Parke & Lacy Co. has been awarded the contract of heating the Garfield school, Oakland, with Smith furnaces.

The Trans-Mississippi Congress.

The Trans-Mississippi Congress, now in session in this city, is engaged in the discussion of various questions of moment to the great West; but at this writing (Thursday) no action of importance has been taken on any of the larger subjects. A variety of resolutions on the silver question have been introduced, and there is no doubt that some strong declaration favorable to silver will be made. River and harbor improvement and the arid lands will of course occupy a large share of attention. At this writing, the Congress has just tabled a resolution declaring that partisan questions shall not be touched; and the inference plainly is that the majority propose to discuss the tariff and the Hawaiian question.

Among resolutions introduced is the following by Grove L. Johnson of Sacramento:

WHEREAS, The Sacramento and San Joaquin rivers, the great waterways of California, are threatened with destruction by debris from hydraulic mining; and

Whereas, The filling of the channels of these rivers by such debris causes immense injury to adjacent farming lands; and

Whereas, The discontinuance of such mining prevents the output of large quantities of gold and the community suffers from the lack of the money which should be made of that gold; and

Whereas, The nation alone can cope with these conflicting conditions; now therefore be it

Resolved, As the sense of this Congress, that the Government of the United States should make sufficient appropriations for and cause to be done such work of impounding mining debris as may permit hydraulic mining without its causing injury to the navigable waters of this State and to adjacent lands, and to provide necessary appropriations for improving and maintaining the navigation of such streams.

Another is:

Resolved, That we are in favor of the passage by Congress of a bill creating an executive department of mines and mining.

Another from the California delegation is:

WHEREAS, One of the most important questions demanding the attention of California is that of cheap inland transportation, and to secure that result the improvement of the navigable rivers, extending over 1200 miles in length, in the State of California, is a matter of imperative necessity;

Whereas, Owing to various causes, the navigability of these streams has been impaired, and the attention they have received from the Federal Government has been insufficient to restore them to their original condition; and

Whereas, Owing to the low prices prevailing for all products of the State of California, the interests of the farmer, fruit-grower, wool-producer, and every other person engaged in shipping produce, requires that relief should be full and speedy; therefore, be it

Resolved, That we urge upon Congress the importance and necessity of improving and preserving the navigable streams of California, and their tributaries, and we urgently ask that the improvement of these streams be done under the special contract system, and that the bill now pending in Congress, introduced by the Hon. Mr. Caminetti, to that end, be promptly passed.

And another is:

WHEREAS, It is evident to all that the completion of a waterway connecting the Atlantic and Pacific oceans will materially encourage commerce and immediately promote increased population and development of the national resources of the West; therefore

Resolved, That this Congress declare it is earnestly and steadfastly in favor of the immediate completion of the Nicaragua canal, and that such canal be controlled directly by the Government of the United States.

To Hydraulic on a Large Scale.

The extent to which hydraulic-mining operations can be carried on under the Caminetti act will be shown by the Quincy Mining and Water Company, owners of the Spanish Ranch mine, Wapaunsee creek, Plumas county. A series of four dams is under construction in the creek, and a storage capacity, aggregating 4,900,000 cubic yards, will be afforded. The dams are very securely built, being rock-filled cribs which are made of huge logs bolted together in the usual fashion. They are models of strength and well fitted for the purposes for which they are intended, that of restraining the debris to be washed from the large and rich gravel deposits above them and preventing it from reaching Spanish creek below. The Plumas *National-Bulletin* reports that these dams will be finished this week. As soon as this work is done, the Commissioners, accompanied by Messrs. O'Brien and Ralston, are expected to go up to Plumas to inspect the completed dams. If satisfactory to the Commissioners, and there is no doubt on that point, a license to mine will be duly granted, thus enabling the company, as soon as the water season opens, to begin washing gravel. The water season will thus be utilized, the debris securely impounded and restrained, thus resulting in no damage to the lands or streams below, and permitting the company to extract and put into circulation much of the gold with which the gravel deposits abound.

The Quincy Mining and Water Company is a large corporation, among whose stockholders are men prominent in financial circles. William E. Hall is president; Dr. James Simpson, vice-president; W. C. Ralston, secretary; James O'Brien, manager; Bank of California, treasurer; A. B. White, superintendent, and Charles R. Thompson, assistant superintendent. Peter Dean, Col. Roberts, Frank Goby, Robert Watt and Mr. Layton are also among the stockholders. The present holdings of the company embrace about 2200 acres of mineral lands and a large ditch

about 40 miles long. It is a mammoth enterprise and will be a profitable investment.

There are others of old California hydraulic mines which afford as good facilities for impounding debris as the Spanish Ranch. It is true that, in this instance, it has been necessary to make a considerable outlay in order to put the mine in shape for operation; but it was either that or nothing. The value of the gravel was known, and it could be demonstrated almost to a dollar what investment would be required to insure certain returns.

It is probable that many of the other large mines which were formerly producers, and which have been idle for ten years or more, would start up but for lack of capital. Many owners of rich hydraulic mines are penniless, or, rather, are unable now to provide means to resume. It may confidently be expected, however, that as soon as the Spanish Ranch and a few others show that, under favoring circumstances, it is possible to operate on a large scale, as in former days, money will be more available than at present.

Mountain Mines—Tuolumne County.

TO THE EDITOR:—The following mines are situated at Arrastraville, about three miles east of the town of Soulsbyville, and deserve attention:

The Donnelly mine is owned by parties in Soulsbyville. It was last worked in 1893, and had splendid prospects. The mine was discovered and worked in 1859 or 1860 and yielded at least \$50,000, the ore paying \$40 to \$60 per ton in free gold. The sulphurets were not saved at that time, as there was no way of working them from which there was not considerable loss, as they were of a high grade. There are several chutes of ore in this mine, and all of good length, and from 18 inches to four feet in width. The mine has been opened by shafts, which are now timbered and in good condition, also by tunnels. Timber for wood and mining purposes can be had on and near the mine, also water with a fall vertically of 200 feet for hoist, mills, etc. It is in slate formation and is accompanied by a dike.

The Easton mine, now idle, is owned by Condey & Cazeretto. The formation is granite. Considerable gold has been taken out of this mine in years past. Some of the ore was very rich in free gold, and some of it had a good percentage of sulphurets. The developments so far made upon this property consist of two shafts. The main shaft is on an incline, and about 200 feet in depth a drift is run north on the vein. There is also a tunnel run in to the north of the shafts, to tap the vein. Good ore was also taken from this tunnel. The vein in this mine is not of a large size. The owners are now running a tunnel to tap the mother vein near the Easton. Ore to the value of \$40 per ton has been taken out of this vein near the surface. It requires 200 feet of a tunnel to tap the vein. About 150 feet of the tunnel have been completed, and should the pay chutes worked above continue down, this tunnel will give them good backs and a large quantity of ore can be taken out, as the vein is of a large size. The Tuolumne Water Company's ditch runs above the mine and this will give good power for mill, etc.

The Duffield mine, owned by E. M. Scanlveno, is situated near the last mentioned mine. The vein runs north and south and is represented to be 8 to 16 inches in thickness, and the main chute is 200 feet in length. The owners claim the ore will run \$36 per ton in sulphurets and \$8 in free gold. The surface was worked years ago for the free gold, but as depth was gained it turned into base ore, and the inability of the owner to put up works, etc., for reducing the ore, accounts for the mine being closed down. It is drained by a tunnel run in from the west, and a drift run on the vein, 150 feet in length, from the drain tunnel. There is timber on and near the property. Good water power can be had from the water company's ditch and the mine can be prospected with small capital.

The Florence vein is now worked by the owners. A tunnel has been run in about 90 feet; a shaft will be sunk from the tunnel and a crosscut of 16 feet will be required from the shaft to strike the vein. I am informed that the ore from the vein paid \$30 per ton, and as soon as opened again the owners expect good returns from it.

The old Good Hope mine, which was first worked several years ago, is now owned by Giekey & Co. There is a vein from 1 to 5 feet in width, and ore prospects good. It has been opened by shaft and tunnel. It should be a cheap mine to work as it is situated near the north fork of the Tuolumne river, and free water power can be had from the river or Basin creek. There is also timber on and near the property.

MINER.

February 12, 1894.

THE announcement is made that Prof. E. E. Barnard is to leave Lick Observatory to assume charge of the new observatory of the Chicago University, near Lake Geneva, Wis. Prof. Barnard has been selected from among a large number of available astronomers to direct the operations

of the great Yerkes telescope, which is shortly to be mounted. He has been identified with Lick Observatory since its inception, and he has done much in a few years to render the observatory famous and place his own name among the first of contemporaneous scientists. His greatest achievement was the discovery of the fifth satellite of Jupiter, September 9, 1892. His departure from California will occasion general regret.

The Proposed Mining Law.

TO THE EDITOR:—I have given careful consideration to the "Miners Association Bill," published in your issue of Nov. 11, 1893, and alluded to in connection with the miners' delegation in your issue of Jan. 20, 1894.

The draughtsmen have done unusually good work. They have resisted the common temptation to make changes merely for the sake of change. Nearly every clause of amended Section 2324 appears in language which has been already construed by the U. S. Courts, and has, therefore, an ascertained judicial meaning. This meaning is not always by any means the popular meaning. The course adopted by the committee tends to prevent litigation by the exclusion of clauses the interpretation of which by the courts might be doubtful.

I would, however, suggest that, in connection with the filing and record of proof of labor, the word "shall" be used instead of "may." The change would make the meaning clearer to the lay mind.

Section 2334, R. S., should be further amended so as to provide that the regulations affecting the survey of mineral claims shall be *and remain* as they existed Dec. 1, A. D. 1884, thereby eliminating at one swoop a mass of vexatious, and, in some cases, illegal regulations of the Surveying Department having no apparent object unless it be to render the procurement of title to mineral lands as difficult and expensive as possible.

The amendments proposed to Section 2335 will be approved by every miner. They express the intentions of Congress at the dates of the acts of 1866 and 1872.

To foster the mining industry and facilitate the development of the mineral sections of the public land was the clearly expressed intention of Congress—an intention constantly over-ridden and thwarted by the corporation-ridden Department of the Interior.

I agree with the committee that in no long time the enactment of a mining code will be necessary. That code should cover procedure in the department as well, and deprive the secretary and his subordinates of the power to make "regulations" (now often made with the effect of practically nullifying the law).

The "regulations" should be a part of the code. When they are so, the scandalous whimsicalities of the department will cease to offend all decent men.

In a recent case in New Mexico two parties claimed parts of one forty-acre tract as coal land, the whole of the same forty being claimed by an agricultural claimant. The same evidence was by agreement used in both cases. The evidence disclosed coal north and south of the forty-acre tract, in such position that the outcrop must necessarily underlie it. Coal was disclosed upon the coal claim comprising an old and rejected mineral survey which crossed the middle of the forty. The sapient solons of the department finally held the central tract within the forty to be coal land, and the two outlying lots north and south of it, which were demonstrated to have acknowledged coal lands north and south of each of them, and developed coal within a few yards of each of them, to be agricultural land. And all this after having accepted entry at \$10 per acre as coal land, which \$10 per acre was duly confiscated by the department, of course.

This bill is a step, and a very important one, in the right direction; but we shall not be satisfied until we get a full mining code, and one which will deprive the Department of the Interior of its enormous powers for mischief.

Lincoln, N. M., Feb. 5, 1894.

* * * *

THE Southern Pacific has done a beneficial thing in reducing the rates on ore shipments from Shasta county. A new schedule has been issued which is as follows from Redding to San Francisco:

Ore and concentrates valued at \$50 or less per ton, \$3.80 or \$45.60 per car load of 12 tons.

Valued at \$100 or more than \$50 per ton, \$5, or \$60 per car load of 12 tons.

Valued at \$300 or more than \$100 per ton, \$6.20, or \$74.40 for carload lots of 12 tons.

Ore lots of four tons or under 12 tons, \$4.56 per ton.

Ore lots of one ton or less than four tons, \$5.32 per ton.

Lots less than one ton, 60 cents per 100 pounds.

Great reduction has also been made in the shipment of base ores.

When we take into consideration that the charge on car load lots of ten tons for ore valued at \$50 or less was \$73, it will be seen that the reduction is nearly one-half.

Chlorination of Gold Ores in California.

Written for the MINING AND SCIENTIFIC PRESS by G. F. Deetken, M. E.

Statements based on assays of small quantities of gold-bearing ores are frequently met in metallurgical journals claiming a loss of gold in an oxidizing roasting of sulphureted material. The conclusions arrived at are mostly based on slight differences in assay value of raw and roasted ore. But unless results are derived from larger and a greater number of assay samples, we might safely depend on the conclusions of Plattner's exhaustive tests—that no gold is lost in an oxidizing roasting.

In a chlorinating roasting, however, the loss of gold in many ores, particularly those carrying tellurium, is very pronounced, and it may be laid down as a rule never to subject a gold ore to a chloridizing roasting, unless previous tests indicate an exception.

An addition of a few handfuls of salt, added a few minutes before the drawing of furnace charge, to give it a chance to decrepitate, appears to have no prejudicial influence on gold, but is a greater help than naturally expected in the following treatment.

The ore discharged from furnace chest remains in a heap until cooled off to some extent.

Of great importance in the roasting of concentrated sulphurets is the proper construction of the roasting furnace, and the temperature at which the roasting is conducted.

Every experienced operator has observed that the results obtained in the first furnace batches of concentrates are invariably above subsequent results; the perfection of roasting—to three-eighths of one per cent of sulphur—being alike in both instances.

The writer considers the encasing of gold particles by slagging of iron, particularly near fire-bridge, the true cause of these observed facts, the steam or moisture of the bottom in first charges preventing such slagging.

It is also a recognized fact that, by thinning down the charge in a reverberatory roasting furnace, the resulting gold bar shows an increase of extraction, the shallow layers of ore allowing a rapid peroxidation of the iron, increasing its refractory character.

A high fire-bridge, high arch, good draught connector, with proper dust chambers, are therefore essential conditions of close extraction of the gold. A low heat in roasting has a number of advantages, which consist in a highly porous condition of the peroxide of iron, favorable to the penetration of the chlorine, in preventing the melting of gold to the globular form, unfavorable to extraction, and also in preventing the inclosure of gold particles by slagging.

The roasted ore moistened with about six per cent of water is impregnated with chlorine gas until it forms heavy white vapors on top of the ore with ammonia. The vats are covered by a light sheet-lead cover, properly sustained on a wooden frame by an overhead trolley, a water joint on the outside of the vat, well tightened by an application of asphalt plastic, poured into the sheet-lead trough, completing the outfit. A second gasing the next day with an equal quantity of gas, the surplus passing into the next and fresh or new charge, finishes the impregnation with gas.

The third day the ore is leached in the usual way. The gold solution is run into a small tank to deposit accidental sands and impurities, and run, when clear, into the precipitating tanks. The gold is now precipitated by a current of hydrogen sulphide. A gas pipe, leading from a puncheon or other larger tank-connector with a water column of at least 12 feet pressure, leads the air pressed through the sulphureted hydrogen generator into the solution and helps to agitate it. A small quantity of waste liquor from the hydrogen-sulphide generator is added to the gold solution after the free chlorine is expelled and the gold partially precipitated. When much copper is present in the solution a fractional precipitation of the copper will find the gold precipitated from the solution.

The writer has experienced a case in which a lot of roasted sulphuret tailings assaying \$8 per ton were regased. The solution from the leaching tanks showed no gold precipitate with iron protosulphate. A precipitate from the solution with hydrogen sulphide gave, when melted with litharge and cupelled, a result of \$8 in gold—the full assay value.

The extraction of fine gold of high caratage by vat chlorination is very perfect. Coarse gold cannot be extracted in the usual time, and is more economically extracted by stamping with quicksilver in battery.

Gold of low caratage cannot be extracted successfully by chlorination. When silver compounds and gold of high caratage co-exist in the same ore, the silver is extracted by subjecting the tailings treated by the above method to a chloridizing roasting with about five per cent of raw sulphurets and treating the roast with hypo solution. The hypo is daily reinforced by an addition of a few pounds of he salt. When the filters consist of burlap and are kept in

proper order, no great loss of hypo is sustained by the action of the chlorine still existing in the solution, as one molecule of hypo neutralizes six molecules of chlorine. The fear of an able writer that tens of thousands of tons of silver ore had been treated in California by hypo solutions, made useless or destroyed by chlorine gas in previous leaching, appears unfounded to the writer. Aside from the fact that such an amount of silver-bearing gold ore was hardly ever treated here, the operators, though mostly of the "muscular amalgamator" class, know that from 60 to 65 per cent of the silver is expected of them under the most unfavorable circumstances.

Additional difficulties arise in the treatment of sulphureted ores by chlorination by the presence of alkaline earths, also alumina, from the graphitic slate of the mother lode of California; also copper and lead. Lime requires a close elimination by concentration so as to be covered by the sulphuric acid formed in roasting magnesia, forming, like lime, a hypochlorite, which has a tendency to form an objectionable cement in the roasted and moistened ore, and has to be removed as far as possible by acid leaching, unless a chloridizing roast on the ore is admissible. The Enreka sulphurets—Grass Valley—in 1865 allowed, with a chloridizing roasting, an extraction of 97 per cent of the gold on sulphurets containing 12 per cent of magnesia (95 per cent of the gold value being guaranteed).

The copper, when in larger quantities, above a few per cent, is extracted from the roasted ore, as first applied by Allain, by diluted sulphuric acid.

Mr. Jory uses Monnier's process of roasting with salt cake, extracting the sulphate and completing the copper extraction as far as possible with diluted sulphuric acid, while Mr. Butters extracts the oxidized copper, as well as the alkaline earths, at once with acids. Mr. Jory finds, with the writer, no difficulty in treating ferruginous quartz carrying limited quantities of lead (up to five per cent of carbonate).

The present cost of extraction of gold by vat chlorination is not above \$7 a ton, with labor at \$2.50, wood \$4 per cord, acid $1\frac{1}{2}$ cents, manganese 2 cents, salt one-half cent per pound in San Francisco and freight at \$20 per ton.

East of the Rockies, the barrel chlorination, by means of acidulated bleaching powder on unconcentrated ore, under the management of J. Rothwell, A. Thies, Langguth and others, has obtained most favorable results.

The *Engineering and Mining Journal* of Jan. 27, 1894, mentions \$2 a ton as a possible Western cost of barrel chlorination. Considering that this estimate includes the dry crushing and tramming of the ore to the works, it certainly appears a most astonishing feat of metallurgical economy.

Concentrated sulphurets, on account of usual presence of elements consuming larger amounts of sulphuric acid, when treated by acidulation of the roasted pulp, are less adapted to barrel chlorination, on account of the limited amount of material on hand, and can be more economically treated by vat chlorination.

Should bromine give as favorable results in gold extraction as chlorine in the treatment of concentrates, the excessive consumption of acid would be avoided. Mr. Godshall's late experiments on this subject appear to speak for nearly equal dissolving power of bromine and chlorine for gold.

G. F. DEETKEN.

Anburn, Feb. 5, 1894.

Making Gas from Coal Oil.

Wm. McDermott has become interested in a new scheme that promises to revolutionize the coal and wood business in Butte, says the *Butte Inter-Mountain*. It is the scheme of making gas from coal oil and using the gas in stoves for heating and cooking purposes. Mr. McDermott has had this system of fuel in use at his residence several days and claims it works successfully.

Two stoves—one a kitchen stove and the other a parlor-heating stove—were fitted up at the M. C. Harris Company's place of business on East Granite street recently, and the gas-heating apparatus was inspected by a number of people. All who saw it were pleased with it. It is claimed this coal-oil gas can be used for half the cost of coal and wood, and will furnish any degree of heat. The equipment necessary is an oil tank containing about 15 gallons of oil. As many pipes as there are stoves in a house may be connected with the tank.

An air pump is also used to pump air in at the top, when a flow of oil is required. The oil goes out through a hole of needle fineness, through a pipe which leads to the grate of the stove. The oil empties into a hydro-carbon burner, which is placed in the fireplace of the stove. As soon as the oil enters the stove, it becomes gas. There is a valve on the oil-pipe to regulate the flow. Many advantages over the old methods of heating are claimed for this coal-oil gas.

Metalliferous Mining in California.

Abridged from Interview in *London Mining Journal*, January 20, 1894.

There are few names more familiar in mining circles in America, and more particularly, perhaps, on the Pacific Slope, than that of Mr. John Hays Hammond, the well known mining engineer. Indeed, his name is almost as well known on this side of the Atlantic as it is on the other, and it may be taken as a general axiom that any enterprise with which Mr. Hammond is associated carries with it the certain hall-mark of being "a good thing." Mr. Hammond was a few months ago appointed to take the management of some very important mining interests in South Africa, and, before leaving for the Transvaal, he paid a flying visit to London. Naturally he gravitated towards the *Mining Journal* office, in order to shake hands and exchange notes with us. In an interview he placed his views on mining on the Pacific Coast, and more particularly gold mining in California, at our disposal.

"Mr. Hammond, what is your opinion of the future of gold mining in California?"

Mr. Hammond had no hesitation in replying to this question. "I think," he said, "California has a very good future before it in gold mining—that is, I should say, in quartz mining."

"And what about the alluvial?"

"There are hundreds of millions of dollars worth of gold in the alluvial deposits, but the great question has been: how can they be worked satisfactorily without causing injury to the farming lands beneath them? I may say in this connection that I was a delegate representing California at Congress. The State of California was losing very seriously by the shutting down of hydraulic mines. People now are almost unanimous as to the advisability of resuming hydraulic operations."

"What about quartz mining, Mr. Hammond?"

"In California it might be said generally, with the exception of a few discoveries made from time to time, that quartz mining has resolved into an economical development of low grade, or comparatively low grade, mining properties, which a few years ago could not be profitably handled. These can now be worked profitably by the introduction of better mining methods and appliances. We are working on lower grade material than has been handled previously. In the early days of mining only such deposits were worked as were extremely rich on the surface. Those deposits have now been worked out. There are, of course, a great many other deposits of relatively low grade which can still be made to pay by better mining methods. That, so far as quartz mining is concerned, is the future hope of California. In point of production the future of quartz mining is more important than that of hydraulic mining, because the hydraulic deposits are of limited superficial area, while the quartz mines extend in depth and may be worked on after the hydraulic mines are exhausted. But still there is a very large extent of auriferous gravel territory which can be profitably worked by hydraulic methods."

"You still consider, then," we asked, "that gravel mining is by no means played out?"

"Certainly not. In fact some of the very best gravel mines of the State were just starting to produce when the process of law shut them down. With reference to quartz mining, the best are mines which have been abandoned and reopened. These mines were closed down through extravagant management, but have been reopened and are now producing very profitably. Two of these I have reopened myself, and they have paid the cost price of the properties and are paying large dividends to-day, simply by the introduction of better and more recent methods of extraction."

"What is the principal system of extraction now being adopted in those districts?"

"The system of gold milling in California is similar to that in Johannesburg. Probably there are some improvements in the details of the process in California, but upon this I am not able to speak very definitely, as I am not familiar with the processes now used in South Africa."

"In the actual matter of extraction of gold, is there any particular process which obtains in California in preference to others?"

"No, I cannot say there is. Our method, broadly, consists of amalgamation, concentration, and the extraction of gold from concentrates by, usually, the chlorination process—that is the old Plattner process."

"Then, apart from gold mining, Mr. Hammond," we asked, "what have you to say about other metalliferous mining industries in and around California?"

"Well, there is little to say. There is not much activity in the other metal mines. Indeed, comparatively little can be said about the States generally in this particular. The low price of silver and the depreciation in the value of lead has necessarily affected the American lead and silver-lead mines. Copper keeps up its price pretty well, and

the copper mines are being profitably worked in many parts of the Union."

Mr. Hammond had, at the time of our interview, just returned from Edinburgh, whither he had gone to present a report to the directors of the Arizona Copper Company. "This property," said Mr. Hammond, "is being worked at a profit, and they may be able to recover a considerable portion of the money which was originally invested."

"Perhaps I should mention," added Mr. Hammond, as we returned to the main thread of the conversation, "that I am the president of the Bunker Hill and Sullivan Mining and Concentrating Company, which is the largest lead-producing mine in the United States. We have had a good deal of trouble with the labor difficulty, but have succeeded in settling that satisfactorily to ourselves, and at present we are closed down on account of the indisposition of the railroad company to make any reasonable rate with us."

"You have your railway rates troubles, then, out West, just as we do on this side," we suggested.

"I should just think we have. Why, we have been paying \$16 per ton, and have been shipping from 80 to 90 tons per day."

"Have you anything to say about the mechanical engineering of your mines?"

"Well, we have the Mona lead concentrate plant with a capacity of 800 tons per 24 hours. Our ore is carried on a Bliechert aerial rope tramway a distance of two miles. It is delivered into the mill and is automatically worked through all the operations of concentration. We employ about 500 miners and surface men, the general average wages being \$3.42 per day per man. The plant was made by Messrs. Fraser & Chalmers, of Chicago, under our specifications, and it is said to be one of the best plants existing for economy in working. We have water power brought in from a distance of three miles in a large flume carrying 10,000 miners' inches, developing about 1000 H. P. at the mill. Our property is what is considered a large low grade mine, and in order to work this property to advantage, continuous operations must be obtained and economy in all directions exercised. The system adopted is the ordinary German concentration process, consisting of crushing by rock breakers and rolls, then sizing by trommels and concentration by jigs, with further classification by hydraulic classifiers, and the concentration of slimes by revolving baddles and Frue vanners."

"Do you favor the principle of a company or syndicate over here that is interested in a property in America sending a man out from here to inspect and report, or do you think it better to engage a man who is already on the other side?"

"I think local experience—experience of the people of the country and the conditions of mining—is a *sine qua non*, together with a ripe judgment as to the value of a property. I think that English engineers, when there is very much at stake, should have some local engineer to co-operate with them in making their inspections and investigations."

"You would not recommend an English syndicate to employ an English mining engineer unless he had some local knowledge in addition to his own?"

"I should prefer to say that I think he should have the assistance of some local engineer. There are a great many English mining engineers who have had extensive experience in our country, and who are therefore good men. I think there is no economy in trying to save the expense of experts in the first instance. If the property turns out a good thing and is taken up on the recommendation of an expert, the fee is insignificant in comparison with the benefits accruing. On the other hand, if the employment of some local engineer should result in preventing the company from investing its money there is a good deal saved."

"How is it that so many of your countrymen come over here to seek capital for their mines?"

"We do not come over here except for money for enterprises requiring large investments. Our own engineers of good standing can raise all the money for the small operations, but it is difficult to get money for very big mines in our country. A good engineer who is successful and has the confidence of the public could get all the money for small enterprises, but when it comes to large amounts he can do much better in England."

THE Sacramento *Bees* Folsom correspondent sends the following: Folsom bids fair to again experience the golden, bustling days of '49. As an adjunct to the renewed interest excited by the many rich strikes made by the miners here, merchants have engaged four-horse freight teams for the purpose of bringing their store supplies from Sacramento, as they claim that during the present hard times freight rates have been increased to such an extent that cheaper transportation can be had by team.

THE miners of the California mine, Eureka district, are on a strike. They formerly received \$3 a day, and now the wages have been fixed at \$2.50.

Hydraulic Mining.*

A REVIEW OF THE INDUSTRY BY DR. HENRY DEGROOT.

In Eight Parts—Part VII.

Lighting the Washing Pits at Night.—As hydraulic mining is, during the water season, carried on without interruption, it becomes necessary to illuminate the pits at night. For this purpose great fires of pitch-pine wood were formerly in use, as they are still by all but the larger companies, some of which have introduced the electric light, the machine used being the Brush pattern, which for running it requires four-horse power. When in use this style of light has been found economical, it affording a much stronger as well as a more reliable light than the pine wood. These machines, everything included, cost about \$2000 set up and ready for use.

The Gold-Saving Implements and Appliances.—The gravel brought down by piping finds its way directly into the sluice, small ditches, when necessary, being cut in the bedrock for conducting the admixture of water, sand, gravel and cobbles into the sluice, the boulders and larger cobbles being retained and piled up in the washing pit. The sluice is a race or flume constructed of planks or cut in the bedrock, usually the former, and constitutes, with its appendages, the principal gold-saving agency in hydraulic mining. Formerly the sluice, instead of a continuous race, consisted of a series of small wooden troughs open at both ends, the lower end of one fitting into the upper end of another. These troughs, each 12 feet in length, were termed "boxes," and a series of these so joined together, was called a string of sluices. When there is so little dirt to be washed that it can be thrown in with a shovel, instead of being piped down and swept in with a strong current of water, as in hydraulic mining, the old style of sluice is still in use. Ground sluicing consists in breaking down the auriferous earth with a pick or crowbar into a running stream, or by water brought in for the purpose, it is washed, and that generally without the aid of a sluice or any mechanical device.

The size of the sluice depends upon grade, quantity of water, and character of material to be washed. Length, within certain limits, on the natural facilities there may be for extending it, and nature of the gravel, some flumes having a total length of a mile or more. Where the purpose of the sluice is the conveyance of the tailings a long distance below the mine rather than saving the gold, it may have a length of several miles, such prolongation of the main structure being called a tail sluice.

As a general rule, the length of a flume should be sufficient to insure a thorough disintegration of the gravel passing through it, and allow the finer particles of gold to settle in the riffles or be caught by the quicksilver.

A sluice six feet wide and three feet deep set on a four to five-foot grade will suffice for running 2000 to 3500 miners' inches. One four feet wide and 30 inches deep, on a four per cent grade, is large enough for 2000 inches, while one three feet wide and two and a half feet deep will do for 600 to 1000 inches, the grades and sizes here mentioned denoting those commonly employed.

The following are the rules to be observed in building the sluice as regards mode of construction, size of box, timber, etc.: For sluices four feet wide and upward, one and one-half to two-inch plank; sills and posts, 4x5-inch scantling. To guard against the leakage, the bottom planks should be of half-seasoned lumber, grooved, and a dry pine tongue inserted; bottom and sides spiked together with nails four inches apart; sills from three to four feet apart according to size of scantling used, which is regulated by the width of the sluice. Thus, a four-foot sluice would require a sill seven feet long of 4x5-inch stuff. The posts are halved into the sills and spiked, every second or third post being supported by an angle brace; bottom planks solidly spiked to sills.

To prevent the bottom of a new sluice from being raised by water collecting under it, the flume should be heavily weighted down by loading the projecting ends of the sills with stones. In tunnels, the ends of the sills can be held down by braces extending to the rock above.

The sluice is paved throughout its entire length with wooden blocks and cobbles, the latter selected of a shape and size suitable for the purpose, wooden blocks being always put in at the head of the sluice. The best wood for these blocks is the nut pine of the scrubby species, the

*This article was prepared by the late Dr. De Groot for the Eleventh Report of the State Mineralogist, just issued; but its publication with that of much other valuable matter was prevented by the necessity of revision and omission, so that the volume might be reduced to reasonable limits. It covers familiar ground, but is, on the whole, a complete and careful review of the industry and hydraulic-mining methods. The article has been furnished this paper by State Mineralogist J. J. Crawford.

fiber of which, being tough and long-grained, "brooms up," that is, wears rough, not smooth like oak and other hard, fine-grained wood. These blocks, which are square, 8 to 13 inches long, are set on end in rows across the sluice, each now being separated by a space of 1 to 1½ inches. They are held in place by riffle strips 1½ inches thick by two or three inches wide. These strips are beld crosswise on the bottom between the rows of blocks by the side lining and secured to the blocks by means of headless nails. This lining consists of a heavy plank nailed inside the sluice. Block riffles are sometimes kept in position by driving soft pine wedges between them and the sides of the sluice. Where both rocks and wooden blocks are used as riffles, they are set in the sluice in alternate sections. While the cobble riffle is cheaper than the wooden and saves the gold about as well, it requires more time for cleaning up, also a steeper grade and therefore more water. After each cleanup or run the blocks are turned end for end and replaced in the sluice, their use being continued until they are worn to a length of four or five inches, when they are no longer deemed serviceable. In placing the blocks in the sluice the alternate rows are fitted so as to break joints.

In some instances scantling placed lengthwise in the sluice have been used for riffles, also worn-out "T" rails, the latter being sought after when obtainable on account of their lasting qualities. When built on a curve, the outer side of a sluice requires to be slightly raised, as in the case of the flume already remarked upon. For the form of sluices having cobble pavement and block riffles, see the accompanying illustrations.

The Grizzly.—The first favorable place along the line

Fig. 2. Sluice with Block-pavement.

Fig. 1. Sluice-boxes: grade 6 inches per 12 feet; sides 36 inches high; 123—compartments.

of the sluice presenting for the location of one of these contrivances is availed of, such place, because of the peculiar conditions required, being not very common. The grizzly consists of a grate of parallel iron bars placed over the sluice-box, its design being to catch and throw aside such cobbles as come down the sluice that are too large to pass through the interstices between the bars. It is this act of flinging off these rocks after the violent manner in which the grizzly bear is supposed to perform a similar act that gave this device its name. To enable this grizzly of the hydraulic miner to well perform its work, there must be a steep declivity close at hand over which the rocks rolling from it can be precipitated out of the way. Beneath this grating is placed a box for receiving the finer material that drops through it, and which is conveyed to a side sluice and by it carried down and returned to the main sluice.

The Drop.—Whenever, along the line of a sluice or the outletting channel below, there occurs a considerable descent, this is availed of to give the gravel a precipitate fall—in the technique of the miner, "a drop," the object aimed at here being the breaking up and disintegration of the cemented gravel. The higher and more abrupt the drop the better. In some instances the outflowing material is, by a succession of falls, precipitated to an aggregate depth of a thousand feet or more, sluices and undercurrents being set between these falls where this is practicable. Illustrations of the drop will be found in several of the cuts alluded to in the text.

THE returns for the Rand mines, South Africa, are at hand for 1893, showing a total production of 1,478,475 ounces against 1,290,000 ounces in 1892. Six years ago, that is in 1887, the total output was less than 35,000 ounces, of a value of about \$560,000, whereas now the rate of production is over \$25,000,000 per annum. The total production of the world for gold in 1892 was over \$130,000,000, so that the Rand mines are now yielding something like one-fifth of the whole production of the precious metal.

The Regulation of Foreign Petroleum Supply.

The Russian petroleum producers have, at a recent meeting at St. Petersburg, agreed upon the following arrangement: The export of petroleum and its sale on the foreign markets shall be left to a committee of five members, of which three were elected at the meeting, viz., the Caspian Company, the firm of Schibajeff and the manufacturer Unanoff; the other two will be elected at Baku, says *Engineering*. In addition to these five, the union elect a number of selling or commercial agents. For export of petroleum without the knowledge of the committee, the manufacturer has to pay a fine. The part of every member in the transactions is fixed by shares, which are again based upon each 1000 poods of petroleum actually exported

American concern is competing more keenly than ever against the Crescent pipe line, which, especially in France, has proved a thorn in the flesh of the Standard Oil Company. This latter company now intends to undersell the former in France, and has built a store at Rouen capable of handling 600,000 barrels per annum. Sites have further been bought for similar installations at Marseilles, Cette, Bordeaux and Havre. A large depot has been erected in Paris, which is being supplied from Rouen. The Standard Oil Company is thus endeavoring to gain the same footing in France, as it already holds in Germany through the German-American Petroleum Company; in England through the Anglo-American Oil Company; in Holland and Belgium through the American Petroleum Company; in the Scandinavian countries through the Danish Pe-

Opening Day at the Fair.

The accompanying illustration gives a view of the inner court of the Midwinter Fair, Feb. 27th. Though there are marked advantages in the photographic method there are also defects. For instance, while the engraving we use shows faithfully the details of construction and the life that comes from the presence of the multitude, it lacks depth and distance and gives no idea of the area of the ground embraced in it. The distant points of the picture are considerably more than a thousand feet from the foreground while the observer would think them but two or three hundred. Aside from this defect the view is true to the scene. The building in the background is the largest of the group, the Manufactures and Liberal Arts

CALIFORNIA MIDWINTER EXPOSITION—PARTIAL VIEW OF BUILDINGS AND GRAND COURT DURING THE PARADE ON OPENING DAY.

during 1892 from Baku via the Transcaspian Railway. The quantity of petroleum which, according to this scale, will be fixed for each producer to supply, is handed over to the committee of five, who sell it for account of the union. The manufacturer who does not deliver the stipulated quantity is bound to make good the loss arising from such deficiency, unless it is caused by fire or other accident. The commercial agents are under the control of the committee, to whom they have to produce monthly accounts of their dealings. The five members of the committee do not receive any remuneration for their work; they are the honorary representatives of the union.

In order to make this arrangement definite, it is required that representatives for at least 80 per cent of Russia's export of petroleum join the union. So far 60 per cent have joined. Negotiations are at the same time progressing between the Russian petroleum exporters and the American Standard Oil Company about dividing the world's market between them in the following manner: The Standard Oil Company should supply 70 per cent and Russia the remaining 30 per cent of the requirements of the importing countries. While the Standard Trust and the Russian producers are thus endeavoring to compromise matters, the

troleum Company; and in Italy through the Italian-American Petroleum Company.

Electricity in Mining in France.

The Compagnie des Mines de Vicoigne et de Neoux has invited tenders from the principal electrical firms for the laying down of an important installation in its mines. The proposals call for the establishment of a central station, which will provide electric power for the different works throughout the colliery. At present only two dynamos will be put in, of which the electrical force will be utilized at a distance of 4400 meters, for the working of five winding gears of from 6 to 14 H. P. Five pumps, operated by electric motors of 5 H. P., will be placed at the bottom of the mine, and electric locomotives, each of 12 H. P., will be employed for the conveyance of coal, at a speed of 12 klloms an hour, along the principal gallery, which has a length of 2000 meters. The mine will also be illuminated by 26 arc lamps and 200 incandescent lamps, each of 16 c. p. This will be the first installation of its kind in France.

THE Maid and Henriette mines, at Leadville, raise 1,728,000 gallons of water per day.

Building. The building on the right is the Mechanic Arts, of whose size the photograph gives no adequate idea.

The fair is opening well. There is much still to be done before it can be said to be complete, but rapid progress is being made. The patronage thus far cannot be complained of considering the incompleteness of the display and the unpleasant weather which has prevailed. About 125,000 people attended during the first week, and daily attendance since has ranged from 6,000 to 15,000. Visitors seem well pleased and surprised at the extent and variety of the display. Each day takes more and more the aspect of a festival. Countless flags and banners are floating from the staffs, music is playing on the Grand Court and in the big buildings, the crowd of merry-makers grows larger each succeeding day, and everywhere is a scene of recreation and pleasure. After this week not a day will pass without a special fete.

The city has already thousands of visitors. The records of the Department of Admissions show that they come from great distances. News has been received that hundreds are on their way from Arizona, New Mexico and Texas. Boats and trains are crowded on their way to this city from Los Angeles and other Southern points.

Marble Deposits of California.

Abstract of Correspondence in the *California Architect and Building News*.

It is my intention in this review of the different marble deposits of the State, to show no favor to any particular material, but, as near as in my power, to make a fair statement of the various kinds and qualities, where they are quarried, and such other information as I may have, when the purchaser can judge for himself after an examination of the different materials. I do not hesitate to say that if there is a deposit of poor marble being worked in California to-day, I do not know of it. They are all good and will take the place of and, in many cases, give better satisfaction than the imported article.

Inyo County Marble.—Near the base of the Inyo mountains, in Owens valley near the lake of the same name, lie what are, perhaps, the largest and most wonderful deposits of marble that have been as yet discovered. It is impossible to describe truthfully these vast deposits of beautifully colored stones.

There is white, black, blue and yellow in pure colors, purple veined, black and gold, making a grand variety of colored marbles, very beautiful for interior decoration. The white marble is perfectly clear, the grain is fine, very compact and will stand great pressure; it is a pure dolomite, therefore, and will take on and retain a very fine polish.

The first two stories of the Mills building in this city are, as well as a greater part of the interior finish of same, done in this material. It is a most creditable piece of work. The main entrance to the building shows what may be done in the way of relief with the white marble.

The black is almost identical in color with the Belgium black marble; it is very difficult to distinguish one from the other when polished. The yellow marble varies from a delicate cream to a dark mottled orange. There are veins of deeper yellow with fern-like markings, similar to moss agate, and it is particularly adapted for furniture and interior decorations.

Inyo Moss Agate Marble.—The color runs from light to dark lively browns with beautiful fern-like markings, and, I understand, is the only marble of the kind known; it takes a fine polish.

A short time ago I was shown a very large collection of fancy colored marbles (in sample) from Italy, and, at the time, I took pains to obtain from the party the pieces of the different varieties on board the vessel at Genoa, Italy, and also delivered here in San Francisco. I found the prices of these colored marbles were far in excess of the Inyo colored material, and while I must admit that there were some very beautiful specimens of marble in the collection from Italy, I say, without fear of contradiction, that the colored marble of Inyo county is fully up to their standard and, in my judgment, much more beautiful.

Amador County Marble.—Situated about six miles from Jackson, the county seat of this county, is a vast deposit of true marble and what is perhaps the truest material (of the marble family) yet discovered in the United States.

As yet there are but two varieties developed, although the vein is uncovered on the face of the hill for a length of about 275 feet and a height of over 400 feet. This marble is variegated in color, one a gray black vein and the other a pure white with jet black veins. The markings of the variety are similar to some of the Italian marble and are far more beautiful, from the fact of the black veins standing out in bold view, while in the case of the Italian marble of this grade the black veins seem to be beneath the surface and are more of a gray than black. A comparison of the two materials leads to a verdict in favor of the Amador marble. A feature of this material which I have not seen in any marble yet discovered in the United States, is that it is very compact, of great strength when put under pressure, yet very easily worked, saws much better than the Italian, and for relief work is much preferable to the imported material. I have talked with several marble workers about this, and in each case they informed me that the Amador marble worked up better than the Italian. The most prominent piece of work done in this material was the interior work and grand stairway of the Stanford University museum. It is really a magnificent piece of marble work. I am reliably informed that samples of this material have been shown to Mr. Vecchi, one of the largest quarry owners in Italy. He pronounced it equal to the best (outside of the statuary) Italian material, and predicted that it would eventually drive the imported article out of the markets of the Pacific coast. This marble received the highest recommendation from the United States supervising architect, of all the different varieties of stones presented to the Government (in samples) for use in the construction of the proposed postoffice in San Francisco.

San Bernardino County Marble.—Here again we have an immense deposit of marble very different in character from that of Inyo or Amador counties, but, at the same time, it is a very fine material of different varieties. There

is black, dark gray and blue—these are variegated—also pure white. The deposit is situated about one mile from the town of Colton, has excellent railroad facilities and an improved plant of machinery for working the marble into slabs, pillars, wainscoting and tiling. A company was organized some four years ago to work this deposit. Their principal marble job was done in the interior of the new Academy of Sciences building in this city.

I am informed that the property or the business of the company has now passed into the hands of two experienced marble men from the Eastern States, and I understand that these men are fully able to handle the quarries as well as the mill.

San Diego County.—This county also contains a deposit of green marble, a beautiful stone very much the nature of onyx. Some time since, the parties owning these quarries started in to open them. I have seen the marble in the rough and finished. It takes on a beautiful polish and is worthy of a place among the best marbles on the market.

In many of the other counties of this State deposits of fine marble have been discovered. None of them have been opened to any extent and are only awaiting capital to develop them.

The Situation in South Africa.

A correspondent of the *Seattle Post-Intelligencer* contributes the following under date Seattle, Jan. 30th, which will doubtless be of interest to many who have contemplated going to South Africa:

Will you kindly insert in your valuable paper the following remarks in regard to South Africa for the benefit of those contemplating going there?

I sailed from London January 20, 1893, for Cape Town, returning the latter part of May, and was only too glad when I reached the States again. Miners thinking of going to Johannesburg would do better by staying at home, even if times are very quiet here. The average of miners landing in Cape Town is about ten weekly, and they are nearly all from England. They nearly all branch out for Johannesburg, and naturally the employers prefer an Englishman before an American, and you will find this in all branches of business, professional or otherwise. The colored people do all the laborious work in the mines, and, as for the positions the white man would take, I suppose there are about 50 waiting for one opening. A good miner can earn \$25 a week, and I think a good miner can earn more here; and then again, he can live considerably cheaper here. He would have to pay in Johannesburg about \$10 weekly. This is speaking of board alone.

When I left Cape Town last May there were hundreds of men in Cape Town from all parts of South Africa looking for employment. Lots of them manage to get down from the interior, and the first chance they have of returning to England, either working their passage or otherwise, they accept. The boat I came back with to London was the *Tartar*. Eleven worked their passage home. They had to refuse many applications. A stowaway is a common occurrence.

Board in Cape Town is \$6.25 a week, and if you wanted a position as clerk, hook-keeper, telegraph operator, etc., they would offer you what they call "a start." That is to say, it doesn't matter how competent you may be, you have to commence with \$5 or \$6 a week, and you think yourself lucky if you can get that. There are, on an average, 100 applicants for each situation.

I took my brother-in-law from England with me. He was earning there \$10 a week, and he tramped around Cape Town seven weeks, and finally got a position. I have just heard from him, and he is at present earning \$6 a week at the same place.

As many people are returning from South Africa as there are going—that is, between 400 and 500 weekly. Men that do get positions, after they have saved, if ever they do, \$200 to \$400, return to England for good.

Employers will not accept any diploma from the United States of any kind, it doesn't matter how high the reputation of the college may be, and any one heading there will only be too sorry he ever left home, as it costs more to get from there than it does to reach there. The whole thing is, there is too much English about it all round, and after having the freedom of this country you will find a great difference between South Africa and here.

There are two or three prices on some of the necessities in Cape Colony, and this is the cheapest place to live: House rent, from \$5 weekly; flour, 6 cents per pound; potatoes, 30 pounds for \$1; butter, 50 cents to 75 cents per pound; bacon, 35 cents per pound.

FIFTY men are at work at the Champion mine, Nevada City, and the 30-stamp mill is kept running steadily. Splendid rock is being taken out, and the mine looks well. As soon as possible the full force of men will be returned to their former places.

Mines for Idle Men.

An odd means of helping the unemployed was devised by the Government of this colony during the winter just ended, when trade was duller and distress more acute and general than in very many years past, writes the Melbourne correspondent of the *New York Sun*. It consisted in simply and actually presenting gold mines to the unemployed workmen. Not only this, but transportation to the mine was furnished, and also tools to work it, and provisions to last until it began to pan out.

There are scattered through the colony auriferous gullies and streams and old diggings that have been worked out, so far as adequate commercial returns are concerned, but which yet may be made to yield a living to any one who will seek hard for it. The living is not good enough to attract gold-seekers in good times, but at a time like the past winter, when thousands of unemployed men, with dependent and destitute families, walked the streets of Melbourne, glad to get even crusts and crumbs, such a living as the old diggings afforded was one to be fought for.

The Department of Mines sent experts to the old mining regions to ascertain where there would be the most likelihood of the unemployed workmen getting enough gold to afford a living. Some regions that would have yielded fair returns to experienced miners were unsuited for the endeavors of the promiscuous workers, willing but unskilled, who were subsisting on charity in Melbourne. To some of the better of those regions, parties of unemployed were sent in charge of one or two experienced miners. But many places were found where unskilled men might get enough gold from the creeks and rivers to afford what would be to them, under the circumstances, a good living.

About 3000 men were sent out by the Government to these old diggings during the winter, and most of them were accompanied by their families. Free railway passes were provided to the station nearest the place where they were to prospect, and, where possible, further transportation was also furnished. On arriving at the diggings, 30 shillings were given to each man for the purchase of provisions and supplies and also a few simple tools. Experienced miners were on hand to show them how to get to work, and remained in the region so long as necessary. Twenty to fifty and a hundred families were located in some diggings. Most of the districts selected for these settlements were along streams, and here was generally found land suitable for raising vegetables and fruits.

The experiment proved quite a success. Almost all the people thus sent out have been making a fair living. Some have had to work hard with little returns and have needed assistance from the Government, but the great majority have done really well. Some of the men have made an average of 20 to 30 shillings a week all the time they have been at the diggings, which was sufficient to maintain their families in quite comfortable circumstances. Few there are who are not able to make at least a livelihood. Some are now returning to Melbourne and other cities to take up their old lines of work, but a great many are remaining at the diggings, satisfied with their present condition, and doubtless in many cases hoping to strike a rich patch.

The Government also settled about 1800 men, most of them with families, on Government land, under the provisions of an act recently passed for the formation of village settlements and homestead associations and communities. Thirty-five such settlements were plotted out, and unemployed men with their families placed on them, with the means of commencing to obtain a livelihood from the products of the soil. The plan of most of these settlements was that of a co-operative community, and great care was exercised to apportion the unemployed among the 35 settlements so that their individual capabilities might be of the best advantage for the common good. The plan was something similar to that of the Hirsch settlements of exiled Russian Jews in Argentina. All these communities are reported to be doing well, and in but few instances have settlers deserted them. The winter climate in Victoria is, of course, very mild, and in July, the coldest month, it is a rare thing for the temperature to fall to freezing.

Temperature of a Coal Bore.

Prof. David and Mr. Slee, chief Inspector of mines, have ascertained the temperature of the Cremorne coal bore, which is 2927 feet deep, with a thermometer encased in iron, owing to the great pressure of the water, which is 1400 pounds to the square foot, says a Melbourne paper. The thermometer was put down three times. On the first occasion, at 2750 feet, it remained two hours. On the second occasion it went a little lower, and remained down 26 hours; and on the third it remained at nearly the same depth for an hour. The readings ranged from 95½ to 96° Fahr. It is concluded from this that at the bottom of the bore, 2927 feet, the temperature will be 100°.

Scientific Progress.

Science of Weather.

B. S. Pague, weather forecast official in charge of the San Francisco station, delivered a highly instructive lecture recently to the students of the Leland Stanford Jr. University. After giving an exhaustive contemporaneous history of the subject of weather forecasting he said, in part:

Weather forecasting is practical meteorology. It is the applying of all known laws to current conditions and deducting probable results.

Simultaneous eye reading observations are made at all Weather Bureau stations at 8 A. M. and 8 P. M. seventy-fifth meridian time (or 5 A. M. and 5 P. M. Pacific time). These observations, consisting of the readings of the barometer, thermometer, the wind vane, the anemometer, the rain gauge, clouds and deductions for the relative humidity, the character of the weather and any special phenomena that might be observed, are enciphered and telegraphed to selected centers, from whence they are again distributed.

At San Francisco we have reports from Chicago westward, from Texas north to the northern stations of the British Northwest. These observations are entered on charts. Lines connecting places of equal barometric pressure, called isobars, are quickly drawn. Lines connecting places of the same temperature, called isotherms, are next drawn. Then on the second chart are lines drawn to show the changes in the temperature during the past twenty-four hours, and on the third chart are lines drawn showing the atmospheric pressure and lines drawn encircling rainfalls and cloud areas. Thus having the three sets of charts prepared, the forecaster sees at a glance where the pressure is the highest and where the lowest; where the greatest and least changes in the pressure have occurred during the preceding twelve and twenty-four hours, when rain has or has not fallen and when the temperature has increased or diminished the amount of clouds. These are the facts known to the forecaster, and from them he is to deduce the probable weather to come.

The atmospheric disturbances affecting the weather in California usually show themselves first in the north off Vancouver island or off the Washington coast. Some few move from the southwest and first appear off the southwest California coast. These latter, however, are rare.

I would call your attention to the daily weather map published every morning and commend it to your attention and study. A careful perusal of it daily, a study of the constant atmospheric changes noted thereon from day to day would soon enable you to deduce your own conclusions and not be dependent on the official forecasts. Observe the movement of the low pressures or storm centers, the influence that the high pressure exerts from one day until the next, notice the position to-day of a certain isobar and compare it with the same isobar of the day following and you will find yourself interested in the movements and deducing valuable conclusions, ever remembering that a southern deflection of the storm or low area will cause rain in California, while an east-

ern movement of the storm will allow fair weather to continue.

On the Pacific Slope, and especially in California, the dry and wet seasons or periods of the year are more definitely marked. The cause of the wet and dry seasons in summer is because the low pressure or storm center moves eastward at such a high altitude that its influence seldom extends farther south than Washington, and at times not to the northern Washington line. In winter these low pressure or storm centers are deflected south, causing the rains which occur.

The Ideal Source of Light.

We have more than once had occasion to notice the fact that it is only by reason of the enormous wastage of chemical or electrical energy which is incurred under existing methods of generating light that the developments, with a view to the commercial application, of practical optics are retarded or completely hindered in many striking and important directions, says the *Optician*. There are not wanting indications, however, at the present time, that we are within measurable distance of discoveries which may rectify these disabilities, so multiplying a thousand fold the possibilities of serviceable or economical use for mirrors, lenses, and other optical appliances. We hope, and the experiences of the past in such matters warrant the expectation, that when this brilliant achievement is arrived at it may be as a result of inventive and scientific acumen on the part of some professional optician. That by the way, however. We proceed to describe one of the most likely directions in which experimental investigations may lead up to this desideratum.

Without necessarily taking much interest in science of what, we believe, has been called the "beetle hunting" order, it seems probable that the minds of most opticians are specially drawn to, and, so far as maybe, specially familiar with the physiological relationships of light. And it has doubtless been anticipated by the reader that what we here refer to as one ideal, or economically perfect, source of light, is that which is elaborated by nature in glow-worms, fireflies, and other living organisms. It is quite popularly assumed that the phosphorescence of these insects is unaccompanied by the radiation of dark heat. But it is needless to explain the reasons why this apparent absence of heat, from such excessively feeble radiations, might be perfectly consonant with the existence of a relatively well marked heat spectrum.

At this point the matter has been taken up by Prof. Langley, who has proved by most delicate spectroscopic observations that the photometric curve pertaining to the Cuban firefly, *Pyrophorus noctilucus*, lies wholly between the limits .45m and .65m with a maximum at .54m in the yellow-green. It is important to notice that, while the terminations of this photometric curve were sharp at the points just indicated, a solar spectrum formed upon the same scale and, in the gross, of equal brightness (or equal dimness) was readily distinguished between .38m and .75m. Cutting off the mere "body heat" of the insect by means of glass impervious to rays over three microns wave length, Prof. Langley has also plotted the total energy curve for

the firefly radiation, and has thus proved conclusively that what we have here is light practically unaccompanied by heat. In fact the insect-light is produced by an expenditure of little more than one four-hundredth part of the mechanical energy consumed for equivalent illumination in a candle flame.

Now, experiments have shown that warmth increases the luminosity of a dead shining glow-worm (the limits of the glow-worm spectrum are .65m to .518m). Electrical excitation, or immersion in oxygen or carbon monoxide, produce the same effect. And that the phenomenon is one of combustion seems to be shown by the fact that carbon dioxide always appears at the luminous surface, while immersion in hydrogen, sulphurous anhydride, carbon dioxide, sulphuretted hydrogen, or a vacuum, extinguishes the light. It should be mentioned that the integrity of the irregularly polyhedral "luminous cells" (.04 to .06mm thick) is essential to the phenomenon. They continue to shine for some time after the death of the insect, and after removal from it, but if crushed their illuminating power is instantly lost.

What is the remarkable carbon compound which undergoes combustion in these cells, and yields "the cheapest form of light"?

Phosphorescence of Paper.

That ordinary paper is susceptible of marked phosphorescence is an observation which was made by Niepce de St. Victor many years ago, says the *Optician*. The experiment by which this was originally demonstrated was to expose or isolate an engraving for about a quarter of an hour, and then to place it in contact with a photosensitive surface. Even after "dilution," as it were, on transference to a second piece of plain paper or cardboard, by contact therewith in the dark, this stored-up light was affirmed to be still capable of producing a negative impression upon a photographic surface.

Vegetable Photography.

The following appeared in "Notes and Queries" some 20 or 30 years ago: "While any fruit, peach, nectarine, or apricot, is yet in a green state, affix an adhesive label, your initial, or any other private mark to the side exposed to the sun. The ripe fruit thus labeled will carry its unobliterated green stamp into the market. This simple operation, should it fail to preserve the fruit, will at least enable the owner to identify it if stolen." Probably the method referred to is one of the first steps that has been made toward the process of "photographing" on leaves, etc.

Electricity With Gatling Gun.

An electric motor attachment has been applied to the Gatling gun which promises not only to more than double the destructive capabilities of that particular machine, but to effect a great advance in the efficiency of all machine guns. The motor is detachable, is of one-horse power, is very small, weighing but a trifle over 50 pounds, and is placed in the breech of the gun, amply protected. The motor increases the present rate of firing, 1200 shots a minute, to more than 3000 in a minute.

A Great Repository of Practical and Scientific Information.

One of the Fullest, Freshest and Most Valuable Handbooks of the Age. Indispensable to Every Practical Man.

Price \$2.00.

Free of postage to any addresses in the world.

THE TECHNO-CHEMICAL RECEIPT BOOK.

Containing Several Thousand Receipts, covering the Latest, most Important, and most Useful Discoveries in Chemical Technology, and their Practical Application in the Arts and the Industries. Edited chiefly from the German of Drs. Winkler, Eisner, Helzetz, Merzinski, Jacobsen, Koller, and Helzetz, with additions by Wm. T. Brandt and Wm. H. Wahl, Ph. D. (Held), Secretary of the Franklin Institute, Philadelphia. Illustrated by 75 engravings. One volume. Over 500 pages, 12mo, elegantly bound in scarlet cloth, gilt, closely printed, containing an immense amount and a great variety of matter.

Price \$2.00, free of postage to any address in the world. A circular of 32 pages, showing the full Table of Contents of this important Book, sent by mail free of postage to any one in any part of the World who will furnish his address.

Production of Colors in Glass.

According to *Die Glashütte*, the beautiful coloring of certain varieties of glass now produced in Germany, and which far excels some of the most noted French specimens, is an art practiced by the glass-blowers at the furnace, by means of an apparatus consisting of a sheet-iron cylinder, 20 inches long and 8 inches diameter, standing vertically, and having a similar cylinder riveted across the top, thus forming a T-shaped muffle. In the lower cylinder is an opening into which an iron ladle can pass; and the horizontal cylinder is provided with doors at either end, the one nearest the operator being so arranged that the blowpipes can be supported, when the door is closed, in a horizontal split running to its middle, the object to be treated being held inside. While the glass-blower is reheating his work for the last time in the furnace, an attendant takes the long-handled iron ladle, which has been heated red hot, shakes into it about a spoonful of a specially prepared chemical mixture, and places the bowl of the ladle quickly in the opening provided for it in the vertical cylinder. The mixture immediately gives off vapor, which rises to the horizontal cylinders, where, meanwhile, the blower has placed his work, supported by the blowpipe, and heated to an even red, turning it rapidly in the vapor; in a short time the object is covered with a changeable luster, is removed from the pipe and tempered like other ware in an ordinary oven, then cut, engraved, painted or gilded, as desired.

Aluminum Boron Bronze.

Mr. H. N. Warren, of Liverpool, England, has been experimenting lately with aluminum bronzes, and has found that the presence of a very small admixture of boron makes a denser and more durable alloy, says the *Scientific American*. This aluminum boron bronze casts and melts well, and is free from some drawbacks met with in working with the ordinary aluminum bronze. Producers of that alloy often complain of the difficulty experienced in obtaining a uniform mixture; for a difficultly fusible alloy sometimes forms on the surface of the molten portion, and, being accompanied by surface oxidation, refuses to alloy with the remainder. The aluminum boron alloy forms at a lower temperature than when pure aluminum is used. In preparing this bronze, Mr. Warren first makes ingots of aluminum containing boron in the same state in which graphite exists in cast iron. These ingots are made by introducing aluminum into a molten mixture of fluorspar and vitrified boric anhydride, which has been heated in an oxy-hydrogen furnace until fumes of boron fluoride appear. The boron is immediately reduced, and it dissolves in the aluminum, and the aluminum is rendered crystalline and brittle thereby. When added to copper in the proportion of five to ten per cent, it forms the aluminum boron bronze in question, which is not brittle. The effect of boron on this bronze would appear to be quite different from that of silicon, which generally ruins all bronzes when present even in minute quantities.

Smoke-Preventing Laws.

The last Legislature of Massachusetts passed a law regulating the smoke nuisance in the large cities. This law provides that in cities of over 300,000 inhabitants, after July 1st of the present year, no person should use bituminous coal for the purpose of making steam in boilers in any building, unless the furnace in which said coal is burned is so built or equipped that at least 75 per cent of the smoke is consumed or otherwise prevented from entering the atmosphere. The penalty was fixed at not less than \$10 nor more than \$100 for each week during which the violation of the law

should continue. In commenting on this, a scientific writer says it is hoped that other States will enact similar laws. It is an easy matter to prevent the smoking of furnace fires, and there is also economy in burning the smoke, which, as everybody knows, is composed of fine coal, which is allowed to escape before it has been properly acted upon by the oxygen of the air.

Process for Coking Dry Coals.

Mr. G. C. Hewett of Washington, D. C., is the inventor of a process for making coke from dry coals and lignites. In describing his process his claims state that during the ordinary process of coking coal which produces a hard, strong and cellular coke, the coal becomes semi-fused and soft, or cokes, in the early stages of the operation, when gases are being evolved freely, and it is this evolution of gas in the soft mass that gives the proper cellular structure to the coke. On the other hand, when a dry coal or lignite is heated, as in the ordinary process of coking, there is no softening of the mass of coal during the evolution of the gases, and no true coke is formed. Mr. Hewett holds that the failure of the many processes for making coke from non-coking coals was caused by the premature evolution of gases during the heating, and that there is consequently no opportunity for the coal to cake. He claims to have also discovered that, by retarding the evolution of gas when the coal is first heated, changes take place in the constitution of the coal which allow it to cake, and a good quality of coke can be produced from a coal that would otherwise yield no coke. His invention consists in bringing about certain changes in the constitution of non-coking coals by heating them at a low temperature under pressure, and thereby giving them the property of caking and then coking them by the ordinary process.

Two Novel Locomotives.

Two engines, built upon what is termed the revolving reaction principle, have been erected, from designs by Alexander Morton, in the works of Messrs. Campbell, Smart & Co., Old Dumbarton Road, Glasgow, says the *Journal of Commerce*. One engine is connected with a large Shiele fan and the other with a high-speed dynamo. It is stated that the former runs at about 1200, and the latter at about 4000, revolutions per minute, with little or no vibration, notwithstanding the fact that both engines are simply lying on a table without securing bolts. The principle upon which they are constructed is that of the oldest engine of which there is any account—the revolving millipede described by Hero of Alexandria, at least 200 years B. C.—which is described as having been an outward flow reaction engine with two diametrically opposite nozzles projecting from a small central globe revolved by the reaction of the steam from the two nozzles at a tangent to the circle.

To Extract Gutta-Percha.

M. Rigole is reported to have discovered a process for extracting gutta-percha from the leaves and twigs of the *Isonandra dichopsis*. It is claimed that this process will insure an unlimited supply of gutta-percha in a few years' time, as it allows of the trees being utilized continuously during the whole period of their existence, instead of being cut down and destroyed for a single yield of gutta-percha, as is now the case on an estate in the Island of Pulo Obin, near Singapore.

Novel Fire Engine.

The Berlin fire department is experimenting with a novel fire engine. The carriage is constructed entirely of papier-mache, all the different parts, the body, wheels, poles, etc., being finished in the best possible manner.

Useful Information.

Effects of Trees on Climate.

As to humidity of air, we find that the annual evaporation within the forests is about one-half of that in the open field; not only is the evaporation within a forest greatest in May and June, but the difference between this and the evaporation in the open field is also then a maximum, which is the saving due to the presence of the woods, says Prof. B. E. Fernow in *Manufacturers' Gazette*. The average annual evaporation within the woods is about 44 per cent of that in the field. Fully half of the field evaporation is saved by the presence of the forest.

The quantity of moisture thrown into the air by transpiration from the leaves in the forest is sometimes three times that from a horizontal water surface of the same extent, and at other times it is less than that of the water. The transpiration from leaves in full sunshine is decidedly greater than from leaves in the diffused daylight or darkness. The absolute amount of annual transpiration observed in forests of mature oaks and beeches in central Europe is about one-quarter of the total annual precipitation.

The percentage of rainfall evaporated at the surface of the ground is about 40 per cent for the whole year in the open field and about 12 per cent for the forest, and is greater under deciduous than under evergreen forests. The evaporation from a saturated bare soil in the forest is about the same as that from a water surface in the forest, other conditions being the same. The presence of forest litter like that lying naturally in undisturbed forests hinders the evaporation from the soil to a remarkable extent, since it saves seven-eighths of what would otherwise be lost.

The total quantity of moisture returned into the atmosphere from a forest by transpiration and evaporation from the trees and soil is about 75 per cent of the precipitation. For other forms of vegetation it is about the same, or sometimes larger, varying between 70 per cent and 90 per cent; in this respect the forest is surpassed by the cereals and grasses, while, on the other hand, the evaporation from a bare soil is scarcely 30 per cent of the precipitation.

The absolute humidity within a forest exceeds that of the glades and the plains by a small quantity. The relative humidity in the forest is also larger in the forest than in the glades or plains by two to four per cent. Forests of evergreens have from two to four times the influence in increasing relative humidity than do forests of deciduous trees. The gauges in European forest stations catch from 75 to 85 per cent when placed under the trees, the balance representing that which passes through the foliage and drips to the ground or runs down along the trunks of trees, or else is intercepted or evaporated. The percentage withheld by the trees, and which either evaporates from their surface or trickles along the trunk to the ground, is somewhat greater in the leafy season, though the difference is not great.

Deciduous and evergreen trees show but slight differences in this respect. More rain is usually caught by gauges at a given height above the forest crown than at the same height in open fields, but it still remains doubtful whether the rainfall itself is really larger over the forests, since the recorded catch of the rain gauge still requires a correction for the influence of the force of the wind at the gauge. In such cases, where over a large area deforestation and reforestation have seemingly gone hand in hand with decrease and increase of rainfall, the possible secular change in rainfall must also be considered.

Telephone Patent Expires.

A dispatch from Washington announces that the patent upon that part of the telephone instrument which is called the re-

ceiver expired on Jan. 30th, so that the implement may become public property. Anybody can use it, and it is possible to construct a telephone system by which this implement can be employed both for the purpose of transmission and receiving, as in its cruder form it originally was.

Ventilation.

The healthy atmosphere in a room is one in which the air is changed to the extent of three thousand cubic feet per hour per adult inmate, says the *Contemporary Review*. The air admitted need not be cold; warmed air, so long as it is fresh, is, of course, preferable to cold air in winter, but in some way the air must be brought in if we are to continue in health. There are various ways of doing this. One is by admitting cold air, so that it is directed upward toward the ceiling, where the air of the room is at the highest temperature; the cold stream is then heated in its passage as it falls to the lower level for breathing. But in large rooms, to utilize at its best this current, there should be in the skirting outlets communicating with a heated up-cast flue, which will draw away the heavy air near the floor, in cases where there is heating by hot water coils, the cold air may be brought in at or near the floor level, and passed through the hot water coils—the outlet for ventilated air being in or near the ceiling—to a heated up-cast flue. In larger rooms or buildings for public assemblies, it may be necessary with either of these systems, to use a fan either to propel fresh air into the room or to draw away the vitiated air.

The great desideratum in the admission of fresh air is cut it up into very fine streams, something in the way water is cut up in passing through the fine nose of a watering can. It has been found that air admitted through a tube or orifice of equal sectional area throughout enters as a cold draught; but if the inlet be through a series of small truncated cones, the smaller section outward, the larger inward, with a wire gauze on the inside, the current is so cut up and diffused that the draft is not felt. By analogy a mass of water entering through a narrow canal, drives all before it, and cuts a channel for itself, but the same quantity passing over a large surface of ground irrigates it. Another important point is not to let the passage of the air be too great a velocity; the gentler the flow the better.

Keeping Warm.

It may not be generally known that, when exposed to severe cold, a feeling of warmth is readily created by repeatedly filling the lungs to the utmost extent in the following manner: Throw the shoulders well back, and hold the head well up. Inflate the lungs slowly, the air entering entirely through the nose. When the lungs are completely filled, hold the breath for ten seconds or longer, and then expire it quickly through the mouth. After repeating this exercise while one is chilly, a feeling of warmth will be felt over the entire body, and even in the feet and hands. It is important to practice this exercise many times each day, and especially when in the open air. If the habit ever becomes universal, then consumption and many other diseases will rarely, if ever, be heard of. Not only while practicing the breathing exercise must the clothing be loose over the chest, but beginners will do well to remember, in having their clothes fitted, to allow for the permanent expansion of one, two, and even three inches which will follow.

Whalebone from Hair.

A process of forming artificial whalebone from animal hair, consisting in subjecting hair to a softening bath, then to a bath of acetic acid, and finally placing the mass under great pressure, has been invented.

STAMP MILLS.

VULCAN WIRE ROPEWAY

for Conveying ORE, CORWOOD, ETC.

HYDER MINE, KENNETT, CAL.

In reply to inquiry as to how Tramway is doing, and prepared to state that it has given ENTIRE SATISFACTION IN EVERY PARTICULAR.

JORDANS TRAMWAY CO., POMEROY, WASH. It will give us great pleasure to recommend your Ropeway and your Company as well to any persons who may be thinking of erecting Ropeways.

VENTANAS M & M. CO. VENTANAS, MEX.

We take pleasure in testifying to the successful operation of the Vulcan Wire Ropeway furnished us by your company. It easily transports the required quantity of ore from mine to mill and has given us no trouble whatever.

VULCAN IRON WORKS.
135-145 Fremont St., S. F.

IMPROVED FORM OF HYDRAULIC GIANTS.

THE ABOVE CUT ILLUSTRATES THE IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture, and which are pronounced far superior to the SINGLE-JOINTED style. We latter, however, we furnish when requested. Prices, discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent upon application.

JOSHUA HENDY MACHINE WORKS, 51 Fremont St., San Francisco.

MANUFACTURERS OF

SHEET IRON & STEEL PIPE
FOR TOWN WATER WORKS.

Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.

NO. 180 BEALE STREET, SAN FRANCISCO, CAL.

Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

Double-Acting Cornish Plunger.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER.

AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, besides doing away with heavy balances. Works with 25 per cent less power. First outlay about one-third less. Suitable to any under or downright shaft. Friction reduced to a minimum. Occupies less space in the shaft. Has been tested about a year and proved to work satisfactory in every respect.

GUARANTEED TO GIVE SATISFACTION.

Special attention is called to this new feature in the drainage of mines and raising water generally, by which a continuous discharge of water is produced on the up stroke and down stroke, instead of on the down stroke only, which is effected by very much less than one-half the weight of machinery now in use.

When the ordinary pump becomes too small for the work it can be replaced by the new one, using the same rod and column, and doubling the discharge of water, a most important advantage in small shafts where there is not room for a larger pump.

Apply to WM NANCE, Grass Valley, Nevada County, Cal.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

Electricity.

Electric Vibration Regulated.

Scientific men have gathered in New York in considerable numbers, writes Holland, the correspondent of the Philadelphia Press, and much that is of interest and one or two things of perhaps the highest importance has been developed at the meetings which these scientific gentlemen have held. Perhaps the most interesting comments are those which followed the delivery of a lecture to a large number of electrical scientists by Prof. Pupin of Columbia College recently.

In the lecture delivered by Prof. Pupin, he showed the results of the months of careful investigation and patient study which he had given to this subject since the brief facts of his discovery were first published, and it was with something of amazement and delight, as well as with many earnest comments as to the effect of this new development of electric force upon the commercial use of electricity, that this lecture was received.

One of the finest evidences of the genius of Joseph Henry was his suggestion of the oscillating vibration of the electric current under certain conditions. Henry, experimenting with the Leyden jar, noticed that a magnetic needle which had been placed in the cellar beneath the room where these experiments were conducted was very strangely affected, it being within what the electricians call the field of electricity. The north pole of that needle was so affected that its position was reversed from the normal, a fact which greatly puzzled Prof. Henry, and which he afterward explained on the supposition that the electric current was oscillating. He proved it, and while the discovery is of no popular interest, it was regarded by scientists as a most important one in that day of early electrical investigation.

It is a development of this suggestion of Prof. Henry's which Prof. Pupin has discovered—such a development as gives him the rank of one having high authority in the field of electrical investigation, although it is too early to say precisely what the commercial developments of this discovery may be. A technical description of it would be impossible in a brief article designed for general reading, but a suggestion of it can be made by the use of comparisons. Pupin, through certain mechanical appliances, is able to control, to regulate electric vibration exactly as he pleases. To use a common term, he can slow up or increase speed, producing exactly the vibratory influence that he desires.

By the use of a second system of mechanical appliances, placed within reach of the deductive influences of the first, he is also able to procure vibratory results which completely harmonize with those developed in the first system. By applying a telephone to this second instrument, any sound which Pupin desires to produce is emitted by the telephone. For instance, if he desires to produce the tone which is caused by striking of the C key upon the piano, he is able to regulate these systems so that the number of electrical vibrations is exactly equal to the number of air vibrations, which cause that tone to be carried to the sense of hearing.

Some of the tones produced by these experiments are exquisite; some of them are discordant, some of them of harmonic suggestion, and it is possible to procure electrically induced tones exactly similar to every sound sensation perceptible to the human ear.

The relations of these two systems to one another in their effect upon the sense of hearing may, perhaps, be best illustrated by suggesting those things which are done when the violin and piano are brought to a common pitch, which means that, the proper note, being struck upon each of these instru-

ments, the identical pitch tone will be delivered by them. The vibrations in that case are carried through the air or ether. Pupin's two instruments have something of this relation to one another. Corresponding and exactly measured vibrations are produced at the will of the operator, causing the same identity of pitch tone which is procured when the piano and violin are, as the musicians say, tuned. Pupin "tunes" his electrical machines.

Effect of Electricity on Steam.

At a recent meeting of the Royal Society of Great Britain, J. J. Thomson described the following experiment, showing the effect of electricity on steam: A current of steam was passed through the middle limb of a T tube, the closed side limbs of which were furnished with delivery tubes and also with gold or platinum electrodes, between which sparks might be passed through the steam. The delivery tubes conducted the gases into two eudiometers, in which the gaseous mixture formed on passage of the sparks was exploded. When the sparks were from 1.5 to 4 millimeters long it was observed that within the limit of error of the experiment the volumes of the excess of hydrogen in the one tube and of oxygen in the other, which remain after the explosion of the mixed gases, are respectively equal to the volumes of hydrogen and oxygen liberated in a water voltmeter placed in series with the steam tube, and that the excess of hydrogen appears in the tube which is in connection with the positive electrode, the excess of oxygen in the tube which is in connection with the negative electrode. When the spark length is greater than 4 millimeters, the first of the preceding results ceases to hold, and when the spark length is increased to over 11 millimeters, the excess of hydrogen, instead of appearing at the positive electrode, changes over to the negative, the excess of oxygen at the same time going over from the negative to the positive electrode. When the sparks are very much longer, about 22 millimeters, reversal again takes place, the hydrogen appearing at the positive electrode. The author finds that when the arc discharge passes through hydrogen and oxygen respectively, the hydrogen behaves as if it had a negative charge, and the oxygen as if it had a positive one.

Ingenious Surgical Device.

A very ingenious apparatus has been devised by Dr. Edward J. Birmingham, surgeon of the New York Throat and Nose Infirmary, for controlling the Edison current so that it can be used direct for galvanic cautery operations. According to his own description of the apparatus, it consists of a rheostat, made of coils of iron wire and a handle. The peculiarity of the handle consists of its having solid conductors, and the circuits, therefore, always closed. It is at all times during the operation under the control of the operator's thumb, and the current can, it is stated, without producing an arc, be cut off from or allowed to pass to the knife instantaneously.

Oil and Electricity.

The improvement of oils of inferior quality, by means of the electric current, forms the subject of a communication recently made to the Paris Academy of Science, describing the results obtained in this direction by M. Levat at the Aix Ecole des Arts et Metiers. After detailing the results of his experiments with olive oil, he described those bearing upon lubricating oils of inferior quality, containing at least five per cent of free acid. He found that the acidity always diminished in the minimum proportioned of 1.5, and by subjecting the electrolyzed oil to a second operation, he was enabled to diminish the acidity to 3.10.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

63 & 65 First St., cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Sorters, etc., including, also, a full stock of chemicals.
Having been engaged in furnishing the supplies since the first discovery of mines in the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.
Agents of the **Denver Fire Clay Co.**, and for the **Morgan Crucible Co.**, Battersea, England. Also for **E. G. Denniston's Silver Plated Amalgam Plates**. The plates of this well-known manufacturer are thoroughly reliable, and full weight of silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "unusually popular" is written in a condensed form, which renders the information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt, will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assay; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Course Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth, 1889. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion; Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Hummer Assay of Silver; Gay Lussac's Method; Volhard's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Ochromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

Machines of all kinds Made and Repaired. Orders Solicited.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Butte.

BULLION MINE.—*New Era*, Feb. 8: The Bullion mill dropped its stamps for the first time on Monday. Everything worked well and the crushing of ore was immediately commenced. Of course, as with all new machinery, some adjustments had to be made, but, taking the weather and everything into consideration, the mill worked to a charm. The bins are full of ore and the mill will be kept constantly running night and day.

A RICH STRIKE.—*New Era*, Feb. 8: A rich strike was made in a shaft being sunk to tap a quartz ledge, about three-quarters of a mile southeast of Forbestown, on Saturday afternoon last. The ledge mentioned is owned by W. Bachmar and A. Basgalapi. They have been at work for some time sinking the shaft, and on Saturday, at the depth of 30 feet, struck the ledge. The first piece taken out showed free gold in considerable quantity, and all the rock taken out during the day was speckled with gold, and also showed considerable sulphurete.

THE DENVER MINE.—*New Era*: The Denver mill has had a steady run since it commenced, about six weeks since, and good results have been obtained. C. D. Lane has purchased the interest of Mr. Lagne in the mine and mill, and they are now owned by Messrs. Price & Lane. It is reported that the capacity of the mill will soon be increased by an addition of ten stamps, making a 20-stamp mill of it.

THE GOLD BANK'S NEW WORKS.—*New Era*: Saturday we paid a visit to the site of the Gold Bank's new air-compressors. The house for covering the plant is about finished, and the workmen are engaged in placing the machinery in position. Everything about the works is very substantially built. The cylinders for receiving the air are in position, and the big fly-wheel ready to be put together. The water pipe which is to furnish the water for the power is laid, as is also the pipe which will conduct the compressed air to the place of operation, but from the magnitude of the work we were unable to obtain an estimate as to the time it will require to complete the works, but were informed that it would be pushed with all possible speed. The works are situated on Forbes' ravine at the junction of Mosquito creek, about one mile from town.

Calaveras.

THE CAMPBELL TO RESUME.—*Prospect*: We learn that operations are soon to be resumed on the Campbell mine on Indian creek. Parties have taken hold of the mine and will endeavor to find out what there is in it. The rock was very rich in places, and the only reason for closing it down was a lack of money to properly open the property. Those who worked in the mine have great faith in its ultimate richness.

THE NORTH STAR.—*Chronicle*: Work is progressing favorably at the North Star hydraulic in Happy valley. A large derrick is now being erected for the purpose of banding the rock in the mine, and a cut is being blasted out in order to extend the flume four boxes more. After the water had been turned on a few days last week a sort of "prospecting" clean-up was made of a few boxes, the result of which far exceeded the expectation of those interested.

El Dorado.

MINA BONNAN.—*Sentinel*: A company has bonded the Willis Gould mine above Iowa Hill, and will proceed to develop the property. They will run the tunnel in about 100 feet farther, and also push the work of crosscutting. The bond is for the period of 60 days, and, if at the end of that time the prospects warrant it, they will purchase the property. A contract has been let, and work will be speedily pushed. The mine is looking exceptionally well, and shows good chances of becoming a dividend-paying property. The gravel is similar to that found in the Morning Star mine.

Humboldt.

ALL IN OPERATION.—*Blue Lake Advocate*, Feb. 8: Miners on the Trinity are as busy as bees just at this time. The plentiful supply of rain that has fallen has provided enough water, and more than enough. However, there have been few if any cleanups, so that they are yet in ignorance of the results of their operations. A China Flat mining man, writing to the *Advocate* under date of the 29th ultimo, stated that the outlook for an exceptionally good season's run was never better; that the owners of claims, while sadly in need of capital to do as they would like to do, are perhaps better prepared to go ahead than the mining season usually finds.

The ditch of the Quimby mine slid out a couple of weeks ago, and that claim ceased operations temporarily. Mr. Thomas Dungan, who has a valuable mine on Trinity, is in eager pursuit of the single standard, and Mr. A. N. Foote is doing likewise. Mr. J. J. Moston, who has been negotiating the past two years for the transfer of a number of good Trinity mines to San Francisco capitalists, is still at work on his big ditch. It is learned that three or four Chinese claims are in operation this side of Hawkeye Bar. Schutze & Coon's mine, a short distance above the mouth of the south fork, is also in operation. There have been few prospectors on the Trinity lately, but an unusual and undesirable profusion of the tramp element, hailing from the scene of operations on the big La Grange ditch.

The snowfall varied from three inches along the south fork to three feet on the mountains.

From Captain Curran it is learned that there is too much water in Three creeks and Willow creek for anything in the way of mining to be done in the beds of those streams.

Mr. Johnnie Brett, who got in from China Flat Monday evening, supplies the information that some of the mines, in view of the fact that only occasionally is there plenty of water, are running both night and day.

Inyo.

MINING EXCITEMENTS.—*Register*, Feb. 10: The town has enjoyed a couple of mild pulsations of excitement since our last issue. The first was caused by the reported discovery by Ruellas and others of the long-lost "Frenchman's mine," in the mountains west of Wetson's ranch, and seven miles south of town. This mine was worked many years ago, and the present locators found upon it an old windlass over a 50-foot shaft. The ledge is said to be six feet wide, but as to its richness there is no satisfactory information at hand. The second stir was created by a rush for a three-foot quartz ledge in the hills six or seven miles west of here, and a mile or so south of Bishop creek. This ledge crops out east of the old Freeman and Coats workings in the same section. The ledge is clearly defined, and the croppings present the appearance of pay ore. Some rich gold float has been found in that locality from time to time, but the lode from which the float came has not been found, unless this present prospect should prove to be its source. Quite a picturesque race took place between John Black and Charley Levy for the location. Apparently there is plenty of mineral ground there, as several locations have been made already.

Mariposa.

RICH ROCK.—*Gazette*: Some very rich rock is being taken from the mine below town. This mine was worked many years ago, when the big mill was in good condition, and it was then known to be rich. But the mine has been idle more than a quarter of a century, and all the old works have fallen into decay.

Nevada.

COE MINA BONNAN.—*Telegraph*: Friday afternoon the Coe mine was bonded and work will be commenced as soon as possible. Messrs. Turner and Bennett bonded the property for parties in St. Paul, Minnesota. The company have plenty of capital and will use it in developing the mine to its fullest extent.

CONTRACT LET.—*W. C. D. Body of Grass Valley* has been awarded the contract to rebuild the hoisting works at the Idaho mine. The new building will be about on the same plan as the one destroyed by fire a few weeks ago.

Placer.

LOOKING WELL.—*Herald*: The Boulder mine at Ophir is looking exceptionally well. The Eclipse has changed management and workmen are now engaged in pumping out the water prior to working the claim.

FOR DITCH WORK.—*Herald*: George Geisendorfer & Sons have commenced a large contract of tunnel and ditch work for the S. Y. Water Co., near Weimar.

PAYING WELL.—*Michigan Bluff Cor. Sentinel*: The Frissell mine, formerly the Morehead mine, is reported as paying handsomely. It is to be hoped that it will long continue to do so, as the superintendent pays the highest wages and is opposed to any reduction.

F. W. LEMENT AND G. W. HOFFMAN, of this place, have taken a contract to run 100 feet of tunnel in the Washington mine at Deadwood, at \$10 per foot.

SUBPANNAN WORK.—*Georgetown Gazette*, Feb. 8: J. H. Pege, who has been engaged in driving the bedrock tunnel to open up the Wilton gravel mine under Cement Hill, has suspended work under unavoidable circumstances. Mr. Pege's reputation as a bedrock gravel miner in Placer county stands among the best.

O. P. WILLIAMS OF THE PENNSYLVANIA SLATE QUARRY, Kelsey district, was in town Tuesday. This company started up operations last November, and will soon have things in shipping order. The quality of this slate is of the very best. The company consists of Messrs. M. G. and Grif. Jones and O. P. Williams. They have leased the land from Mr. Hanley.

An important strike of rich gold-bearing quartz was made this week near the Brown mine, south of the Taylor, by the Dacon Bros. and Sam Collins.

Plumas.

THE PLUMAS IMPERIAL.—*National Bulletin*: Under the direction of Supt. Thomas, the work of constructing the rock dam across Rock creek is progressing favorably. The structure is about 50 feet long and in a narrow gorge, with a solid rock foundation. Nine men are employed blasting rock and putting it in place. The site is a very favorable one for building a permanent dam and thus making a large reservoir for impounding debris from the hydraulic mines above, which will be operated as soon as the dam is finished and the mine gotten ready for work.

SINKING BEGUN.—*National Bulletin*: Last week the sinking of the shaft to tap the Elizabethtown channel under the Kellogg ranch was begun, but, owing to the incapacity of the old engine in use, work had to be suspended a few days. The engine from the Lee Bros.' sawmill will be substituted. It has been taken to the Greenville foundry in order that the cylinder might be "bored" out. When this machine is put in place, work will be resumed. Everything will be in good shape for rapid and effective work. A good start has been made on the shaft. It is now down about 12 feet, and there far there has been but little water to contend with. It is thought the shaft will have to

be sunk in the neighborhood of 100 feet to reach bedrock. Some drifting may then be necessary to reach the center of the channel, which is considered one of the richest in this part of the State.

San Bernardino.

LOOKING WELL.—*Shaft*: The Bronze is looking splendidly now. A good deal of work is being done on it, and it is being done in a scientific manner. The company are to be complimented for the excellent judgment shown in the selection of Mr. Charles Saurhrey for foreman, and they are to be congratulated because of the fact that he is in their employ.

AT CAMPBELL'S.—*Shaft*: Active operations in sinking were commenced at the Boomerang on Tuesday morning. Foreman McAdams, having received orders to prepare for sinking, got to work as usual and kept at it night and day until everything was ready, and then work was commenced with three shifts. Shaft No. 2 has been straightened at the 200-foot level, where the vein left the angle that it had been following and became vertical. It is expected that each shift will do over a foot of work. At the mill everything is progressing rapidly. The battery frame has been erected, the foundation for the engine has been laid, and the engine is in place. The foundation for the boilers is now being laid. The large water tanks, three in number, have been erected. The road to the mines is being graded, and will very soon be completed. Large crews of men are kept at work under competent foremen, and consequently much is being accomplished.

Siskiyou.

ABUNDANT WATER.—*Yreka Journal*: The quartz mills in the Salmon river section, and the hydraulics, are all in operation, with an abundance of water for the power wheels and giants to last until late in the summer, and good returns are anticipated. The great amount of rain and snow this season up to date on the high mountains will enable the millmen to keep the mills running until later than the average time for resort to the steam power. We have two months more winter yet, to add to the snow on the mountain peaks, which affords a good fountain in keeping the little streams well supplied with water by the melting snow under the beat of the sun and during warm spring showers.

The lessee of the McConnell & Quinne claim at Klamath river, near the mouth of Humboldt creek, has an eight-horse power engine on the ground, and is busily engaged in making preparations to commence active operations as soon as the river is down to its normal stage or summer level. This engine will probably be stout enough for the hoisting derrick and pump, and run the dip wheel by the current or construct a ditch for keeping the sluices supplied to wash the gravel from bedrock.

The Pokegema Mill Co. intend rafting lumber down the Klamath river to the various mining companies for the construction of wing-dams, water-wheels, etc.

NEVADA.

Washoe District.

SUMMARY OF COMSTOCK OPERATIONS.—Superintendent Lyman's official letter from the Consolidated California & Virginia mine for the week ending Feb. 9th contains the following: "1650 level.—In our workings and from the drift run north from the foot of the upraise which was carried up from the sill floor of this level, we have extracted a few tons of ore of average assay value. The drift running from the east crosscut No. 1 from the drift run north from the winze (down 52 feet), at a point 40 feet north from the winze, has been advanced 19 feet; total length, 217 feet; face in porphyry and some quartz. At a point 20 feet back from the face, in prospecting upward, have extracted a few tons of ore assaying \$25 per ton. The east crosscut No. 2 from the drift run north from the winze (down 52 feet), at a point 126 feet north from the winze, has been advanced 10 feet; total length, 107 feet, terminating in porphyry formation. Total quantity of ore extracted from all parts of the mine was 45 carloads—about 43 tons—mostly from our workings near the winze (20 feet down); average assay value, \$33.20 per ton. The southwest drift (the Rule drift) from the 1000-foot station of the Con. Virginia shaft has been advanced during the week, in the same course which has heretofore been followed, a distance of 62 feet; total length, 580 feet; the face is in a formation of porphyry, clay and quartz, which carries a small assay value. A distance of 45 feet now intervenes between the face of the drift and the point where connection will be made with the drift which is coming from the Best & Belcher side. That drift has been reopened to a point 20 feet within the Con. Virginia ground, leaving 200 feet more to be repaired to meet the Rule drift, and it is now making good progress toward the connecting point."

In the Ophir mine, on the 1465 level, the north drift is in 124 feet. The face is in porphyry, clay and a little quartz carrying a small assay value. An advance of 61 feet has been made during the week in reopening and re timbering the central tunnel, making the total length of the drift reopened from its mouth 506 feet. Have continued jointly with the Mexican Company the work of making repairs to the main shaft. In the Mexican mine, on the 1465 level, the west crosscut from the south drift from the top of the raise 45 feet up is in 207 feet. The face is in porphyry carrying clay separations. On the 900-foot level of the Union shaft the Union Consolidated and Sierra Nevada joint east crosscut from the north drift from the joint west drift is in 45 feet and has been passing through tough clay. The Sierra Nevada south drift from the intermediate tunnel in Cedar Hill is in 416 feet and the face is in hard porphyry. In the Andes mine west

crosscut No. 3 from the north drift on the 420 level has been advanced 10 feet in quartz of nominal value.

In the Best & Belcher mine the east crosscut on the north boundary, 900-foot level, is in 328 feet, and the face is in hard porphyry. On the 1000 level the northeast drift, which was run from the main north drift, has been cleaned and repaired 126 feet; total length 140 feet. Have done some repairing on the 400 level during the week. In the Gould & Curry mine, on the 200 level, the west crosscut, started in northwest drift, 432 feet from the main west drift, has been advanced 10 feet; total length, 882 feet; face in hard porphyry.

In the Hale & Norcross mine they continue to stoop out ore from the winze below the 1300 level, and extracted during the week two cars of ore assaying \$35.15 per ton per car sample, and 26 cars of ore; average assay per car sample, \$20.63 per ton. In the Chollar mine they are reopening the main incline below the 930 level. Extracted and sent to the mill the past week 163 tons and 400 pounds of ore from the 100 level. Milled during the week 150 tons. On hand at mill 73 tons and 800 pounds. Average battery assays, \$20.51; average car-sample assays, \$21.41. Shipped to the United States Mint, Carson, 446 pounds of crude bullion. In the Potosi mine the south drift on the 450 level is out 103 feet, face in clay and quartz. In the east crosscut, 300 feet south of the north line, 750 level, no work has been done on account of making repairs to the south drift, which are completed, and work resumed in the crosscut Saturday. Are yet engaged in making repairs to the south drift on 930 level. In the Bullion mine the west drift from the station, 820 level, Ward shaft, is out 525 feet from the shaft; face in clay and porphyry. At the old Alpha shaft they have finished repairs to the hoisting frame. The shaft is retimbered a distance of 70 feet below the surface. In the Alta mine they have advanced the upraise 30 feet; total height, 30 feet above the track; face all in quartz yielding low assays. Stopping above the 725 level, west of track, following a stringer of good ore; saved about three tons; assay value, \$40 per ton.

Ferguson District.

FULL OF PROMISE.—The Ferguson district, although in the incipient stage of development, gives abundant promise of becoming a great gold producer, says W. S. Godbe. Large shipments of gold quartz are now being steadily made by teams to Milford, 150 miles distant, and thence by rail to Salt Lake, the proceeds of which, after deducting hauling and smelting charges, still leaves a margin of profit to the mine owners. The last few carloads sent to the Monitor netted at the mine \$75 per ton. The quantity of second-class ore already uncovered, carrying from \$20 to \$60 in gold per ton, is undoubtedly great, and, with suitable milling facilities at or near the mine, would yield large returns.

The opportunity for the district now is to secure the largest and richest of the mines, such as the Monitor, Jimcrow, April Fool and Magnolia, and provide adequate means for the cheap transportation and reduction of their ores, which the present owners are unable to do. An 80-stamp modern mill would not be too large to begin with, the returns from which would be such as to warrant more of similar capacity. The district is entirely new and very extensive. It is there that we look for the silver, or, rather, the golden "lining" to the dark cloud that at present obscures our horizon.

Silver Star District.

RASUMEN SINKING.—*Walker Lake Bulletin*, Feb. 7: Ed Brown has resumed sinking the Herd Scramble mine. He is now down over 20 feet. There is seven feet of solid ore in the bottom. The grade of the ore seems to be improving.

Frank Pedrazzi has over three feet of \$50 ore where he is sinking.

John Fleming and company have three men at work, and their ledge shows between three and four feet wide of \$60 to \$75 ore.

The Orphan Boy, belonging to the same company, continues to show well. It has three feet of \$40 ore.

Grassie's Julia mine is considered to be a bonanza.

The Fottler mine, belonging to Douglass & Co., is showing up big in high-grade ore.

E. Dunlap's prospect is showing up a large vein of \$30 to \$40 ore.

There are about 50 men in the diggings.

Tom Pepper owns the springs and is going to build a large reserve reservoir.

The camp has been named Douglass, in honor of the recorder, W. J. Douglass.

The mines are eight miles from Soda Springs and 12 miles from Rhodes.

OREGON.

GOOD FOR PLACERS.—*Jacksonville Times*, Feb. 11: The weather is propitious for the placer miners and they are in a happy frame of mind. The prospects for an extended run are good.

Lewis & Hampton, who own the Dyserf placer mine in Grave creek district, have a sawmill of their own in operation, getting out timber to flume a 15-mile ditch. This will prove to be valuable property.

Jas. McDonough of Tolo, while in Jacksonville a few days since, exhibited some rich specimens of quartz which he had picked up at his placers near Fort Lane. These mines are just below the McDonough ledge, from which considerable gold has been taken in days gone by.

T. J. Chapman, receiver of the Hammerly mine, is in town to-day and brought with him between \$1100 and \$1200 worth of amalgam, the product of the mine from a run of a few days. Mr. C. is now engaged in fixing up the mill for another run, and has nine men employed at the mine.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

TICKET AND TIME-TABLE HOLDER.—Faxon D. Atherton, San Francisco. No. 513,749. Dated Jan. 30, 1894. The object of this invention is to provide a convenient device with independent concealed and open compartments, for the purpose of containing a ticket which may be easily removed from the concealed compartment, and for containing a time table in the open compartment through which the face of the table is constantly exposed. It consists of a case of leather or other suitable material having a closed back, open front and intermediate diaphragm all stitched together at the edges and bottom so as to form a double compartment with a suitable cut away portion at the top to allow the ticket to be easily removed.

WIRE TIGHTENER.—Wm. B. Fielding, San Jose, Cal. No. 513,906. Dated Jan. 30, 1894. This invention relates to a device for stretching telegraph, electric and other wires which are stretched between supporting poles at a considerable distance apart. It consists of heads having projecting forks or yokes between which are journaled poles and a strap which is secured at one end of one of the forks passing around the poles so as to give the proper amount of power to draw the heads toward each other. Either one or both of these heads are provided with a peculiar clamping device which is adapted to grip the wire, so that two opposite ends of wire may be drawn toward each other to any degree of tension, and held until the ends are properly joined. Or if the wire is to be drawn in one direction, the opposite end of the device is provided with a means for securing it to the post or pole toward which the wire is being drawn. A peculiar locking device and pin are used for holding the strap when the wires have been drawn to the proper degree of tension.

MECHANICAL MOTOR.—P. Frichette, Sheridan, Cal. No. 514,356. Dated Feb. 6, 1894. This invention relates to a class of intermediate devices which is designed to increase the efficiency of a pump by increasing the number of strokes with relation to the movement of the initial driving mechanism. It consists of a segment and an operating lever arm, the segment engaging the pinion of smaller diameter so that the movement of the segment will cause as many revolutions of the pinion as desired. The pump is connected with a crank shaft at the opposite end of the pinion shaft, and is thus easily operated.

EXTENSION STEP-LADDER.—Edwin W. Hammon, Davisville, Cal. No. 514,223. Dated Feb. 6, 1894. The object of this invention is to provide a step-ladder which is easily arranged to be used in that manner by means of connecting bars, and has also a means for uniting the two parts at the top. If the ladder is to be extended in the form of a single continuous ladder the top is disconnected, the sides of the bracing ladder are brought into line with the lower step-ladder portion and are held in position by clamps which slide upon the side bars of the step-ladder, these side bars being turned up so as to lie alongside of the two parts when the ladder is extended and the two parts are thus clamped together at the joint so as to be sufficiently rigid to be used as a common street ladder. The device is easily interchangeable and is very convenient for orchard, farm and other work.

HOLDER FOR TOILET ARTICLES.—Wm. M. English and Frederick E. Gladwin, San Francisco, Cal. No. 514,182. Dated Feb. 6, 1894. This device consists of three wire frames so hinged and connected together that they may form a triangular standard upon which a mirror may be supported, having brackets at the rear for supporting a roll of paper, and these frames may be turned into various positions with relation to each other, so as to either rest upon a table hung upon the wall, with one side or the other outward, as may be desired. The frames are also provided with brackets for supporting brush, comb and other toilet articles, also pens, pencils, and desk and office furniture. And when used as a table standard it may support a calendar or any memorandum pad, if desired.

MERRY-GO-ROUND.—Jacob Thompson, Benicia, Cal. Assignor of one-half to T. D. Montgomery of Benicia, Cal. No. 514,393. Dated Feb. 6, 1894. The object of this invention is to provide a rotary travelling frame supported upon wheels and movable about a central pivot posts having seats or saddles so arranged that by means of crank axles the rider can exercise his own power for propulsion of the machine. The machine is so arranged that by shifting the bearing wheel to or from the center a greater or less speed may be attained. It is especially designed to be set up economically, for the amusement of children at home.

Complimentary Samples.

Persons receiving this paper marked, are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

THE ORIENTAL GAS ENGINE

IS THE BEST, because it combines simplicity of construction with power and economy in space. It can be run with natural or manufactured gas or gasoline at a cost of 20 to 25 cents per horse power per day.

It can be used for pumping purposes, as well as for all purposes where a perfect engine is required, with the advantage of lessening the risk of explosions. No licensed engineer at a high salary needed to operate it.

Send for circulars and prices if a good safe engine is what you need.

The Oriental Launch is Perfection.

Market Reports.

The Markets.

SAN FRANCISCO, Feb. 15, 1894.

The silver market during the week has been in a very unsatisfactory condition. Prices are slowly approaching the lowest figure ever reached in New York; and in London they have already passed the lowest previous figure. The explanation, of course, lies in the abundant supply and the restricted market for silver. The output in the Mexican and South American fields is as large as ever; and Australia shows apparently very little falling off in production.

The Coinage for January.

The several Mints of the United States coined during the month of January all the styles of coin known to the American system except four. The aggregate coinage for the month and for the current fiscal year are as follows:

	For January	July 1 to Jan. 31.
Double Eagles.....	\$ 6,655,600	\$23,555,160
Eagles.....	4,466,000	19,866,330
Half Eagles.....	8,360,765	37,513,322
Quarter Eagles.....	319,000	1,735,163
Standard Dollars.....	62,000	289,173
Half Dollars.....	75,200	387,147
Five Cents.....	49,600	249,869
Cents.....		

Totals.....\$11,637,400 \$55,490,288
Same time in 1892-93.....4,531,900 \$25,224,918

Quicksilver Trade.

The receipts of quicksilver at this port for January were 327 flasks, against 2243 flasks for the same month last year and 1704 flasks in 1892. The exports from this port by water in January were as follows:

	Flasks.	Value.
New York.....	1,000	\$ 30,000
Mexico.....	200	6,000
Central America.....	100	3,050
British Columbia.....	31	992

Total.....1,331 \$ 40,042
In 1892.....3,208 133,260
In January, 1893, the shipments to New York were 2600 flasks, valued at \$107,900.

NEW YORK, Feb. 15.—Following are the closing prices for the week:

	Silver in London, N. Y.	Copper.	Lead.	Tin.
Thursday.....	29 3/4	63 1/2	9 7/8	3 25
Friday.....	29 3/4	63 1/2	9 7/8	3 25
Saturday.....	29 3/4	63 1/2	9 7/8	3 25

Mining Share Market.

SAN FRANCISCO, Feb. 15, 1894.

Trade in Comstock shares during the past few days has shown considerable activity. Yesterday Consolidated California rose to \$4.10 and Ophir to \$2.90. Potosi sold at as high as \$1.15. This morning there was still greater activity in the Comstock shares, and prices were higher along the line. Toward noon the sharp advance in some of the stocks drew out sales from people who wished to take their profits, and the market receded sharply. The market, however, had a good tone.

The north-end stocks continued to be the favorites with buyers, but there is the same steady absorption of the leading middle and Gold Hill stocks that has been in progress for several days past. The attendance in both Boardrooms is the largest for quite a time past.

The preparatory or "dead work," such as repairing drifts and making air connections, in the Consolidated California and Virginia, Ophir, Mexican, Potosi, Belcher, Crown Point and other leading Comstock mines will soon be finished, and the operations may be of a more vigorous character. A very energetic search, it is said, will be made for ore, and out of so many interesting exploitations operators are of the opinion that some good will come.

—Placer county is to have an \$80,000 court house.

Coast Industrial Notes.

—San Jose is providing support to its unemployed by placing them at work on the streets.

—There are in Arizona 12,000,000 acres of surveyed land and 34,000,000 acres of unsurveyed land still open to settlement.

—A Salinas authority predicts that the Monterey & Fresno railroad will be built in four months if the right of way is secured before the close of this month.

—The City Council has condemned the Phoenix Opera House as unsafe, and ordered its removal. The building, a three-story brick, was erected in 1888 at a cost of \$25,000.

—While workmen at a limekiln near Gila City, A. T., were prospecting for limestone recently, they found a vein of fine marble, 40 feet wide and equal to the best that Vermont produces.

—The schooner Corona, Captain McAllen, is ashore in Useless bay, thirty miles north of Seattle. She is loaded with lumber for San Pedro and, it is believed, will go to pieces.

—The Humboldt Electric Light & Power Company of Eureka denies a story that the electric light companies are about to consolidate in order to raise the prices of their lights.

—There is a prevailing idea in local shipping circles that marine business is on the mend. Passenger travel on the coast is certainly improving, but that is a result of the Midwinter Fair and the excursion rates offered by the steamship people. Every steamer to arrive, both north and south, is taxed to an extent unknown before in years, and the excess is largely traveling on special round-trip fair tickets. Even the San Blas, from remote ports between Mexico and Panama, came in one morning last week with nearly a hundred passengers—a larger number than any Pacific Mail boat on the southern route has carried for a long time.

—An exhibit of timber from Puget Sound for the Midwinter Fair has arrived from Tacoma on the ship Dashing Wave. There are two of the sticks, which were discharged recently, at Berry street. The largest is a clean stick of Washington pine 117 feet long and 24x24 inches square, and the other is 20x20 inches thick and 105 feet long. Both of the immense timbers are from Harrison's mill at Tacoma, which sent similar exhibits to the World's Fair. The timber which is 117 feet long contains 5,616 feet, board measure, and weighs ten tons. It is the largest piece of timber ever sent here and has not a single knot in it. It will be one of the most interesting single exhibits at the fair.

—The stockholders of the Market-street Railway Company held their annual meeting Tuesday and transacted much important business. It was voted, in order to meet the requirements of the new system, to issue \$17,500,000 in bonds, to be secured by a consolidated mortgage, covering all of the various properties of the company. With this amount the outstanding bonds—amounting to \$7,000,000—will be redeemed either at maturity or before, and the remainder will be used from time to time as the necessity may arise for the construction and equipment of new lines and the improvement of the present system. The bonds will bear five per cent (the old ones bore six), and will run 49 years.

—According to General Casey, Chief of Engineers, there is still available \$25,000 for the operation of the snag boat between Sacramento and Red Bluff. The snag boat will be ordered between Red Bluff and Redding to make that portion of the river navigable. The California Commission will endeavor to incorporate a clause in the River and Harbor bill to have engineers make a survey of Napa river, between North and South Vallejo. If the commission can induce the River and Harbor Committee to grant an appropriation of \$50,000 for a snag boat between Red Bluff and Sacramento, with the \$25,000 already available, they say the river could be put in excellent condition.

—Recently the Mayor and Common Council requested the San Jose Light and Power Company and the Electric Improvement Company to furnish a statement of the financial affairs of each company for the purpose of regulating the rate to be charged by the companies. It is claimed that the rates for light have been so high for five or six years that, as a result, the city is now paying about \$2000 per year more for its street lights than the lowest bid was for. The companies are equally determined to resist this move, for in a communication just filed by the Light and Power Company, a few figures designed to show that the company's investment is only fairly profitable were presented under protest, while the Electric Im-

provement Company hegs leave for two weeks longer to think over the matter.

—The engineering and machinery firm of Rix & Birrell is before the courts with a petition to be declared insolvent. One member of the firm desires the declaration and the other protests against it. The representation to the court is that the liabilities are \$18,752, the assets \$11,010. The principal creditors and the amounts due them are as follows: P. H. & F. M. Roofs & Co. of Indiana, \$2,843; Bradford Mill Company of Ohio, \$1,466; Brownell & Co. of Ohio, \$2,721; Prentice Brothers of Massachusetts, \$1,017; McIntosh & Seymour of New York, \$1,443; Hoover, Owens & Rentschler of Ohio, \$1,449. The firm also owes \$1,290 to the Donohue estate for the rent of the premises at 48, 40, 42 and 44 Fremont street. The request to be declared insolvent was filed Tuesday by Mr. Birrell. Mr. Rix's name did not appear on the petition.

—The Los Angeles Herald learns that Mr. Huntington has decided to go ahead with the work of making Santa Monica a thoroughly protected harbor, whether the Government assists him or not. To this end he has had plans prepared for a breakwater, to be built of rock, extending for half a mile outside the big wharf at that point. These plans were completed a few weeks ago, and outline a fine piece of protective engineering against the power of the sea. An idea of the completeness of the work and its extent can be had from the estimates which accompany the specifications, and which call for an expenditure of \$1,500,000. It was for the execution of this project that the branch line to Chatsworth Park in the San Fernando valley was recently built. At that place is a quarry of stone peculiarly adapted to resist the action of the water, and from here will be carried the huge blocks to be used in constructing the breakwater. As this will extend out for half a mile, a large portion of the big wall will have to be built up for 40 or 50 feet under water.

STOCKHOLDERS' MEETING.

Office of the Superior Mill & Mining Co.

NOTICE is hereby given that a meeting of the Stockholders of the Superior Mill & Mining Company will be held at the office of the Company, No. 323 Front St., Room 2, on Saturday, the 3rd day of March, 1894, at the hour of 2 o'clock P. M., for the purpose of electing a Board of Directors to serve until the next annual meeting, and until their successors are elected, and for the transaction of such other business as may come before the meeting.

The Annual Meeting not having taken place at the time appointed, and no call therefor having been made, the meeting is called and notice thereof given to the Stockholders by the President of said Corporation.

D. L. MUNSUNG, President.
Office, Room 2, 323 Front St., San Francisco, Cal.

Cal. Debris Commission Notices.

THE CALIFORNIA DEBRIS COMMISSION having received petitions to mine by the hydraulic process Daniel W. Albert in the Union mine, near Brownsville, Yuba Co., to deposit tailings behind dam in dry ravine; James Gusten Gump in the Campo mine, near Brownsville, Yuba Co., to deposit tailings behind dam in a ravine; from J. M. Wetmore in the Herring Ravine mine, near Brownsville, Yuba Co., to deposit tailings behind a dam in the Letson ravine; from James Gordon in the Motor mine, near Brownsville, Yuba Co., to deposit tailings in old hydraulic pits; from Crane Bros. in the old Sharon Valley, near Brownsville, Yuba Co., to deposit tailings in old hydraulic pits; from the Spring Gulch Mining Co. in the Spring Gulch mine, near Andrus, Calaveras Co., to deposit tailings behind dam in Chilly gulch; from Joseph Snow and in Snow Bros' mine, near Nevada, El Dorado Co., to deposit tailings behind a dam in Weber creek; and from H. P. Havens in the Green Meadow mine, near Glenn, Calaveras Co., to deposit tailings behind dam in dry ravine, give notice that a meeting will be held at Room No. 92, Flood Building, San Francisco, Cal., March 6th, 1894, at 1:30 P. M.

Assessment Notices.

GOULD & CURRY SILVER MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Virginia, Storey County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors held on the 31st day of January, 1894, an assessment (No. 73) of Fifty (50) Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary at the office of the Company, Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 31st day of March, 1894, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on THURSDAY, the 23rd day of March, 1894, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Directors.

ALFRED K. DUKBROW, Secretary.
Office—Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

OCCIDENTAL CONSOLIDATED MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Virginia, Storey County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors held on the 15th day of January, 1894, an assessment (No. 15) of Ten Cents (10c) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the company, Room 69, Nevada Block, 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of February, 1894, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on WEDNESDAY, the 14th day of March, 1894, to pay the delinquent assessment, together with the cost of advertising and expenses of sale. By order of the Board of Directors.

ALFRED K. DUKBROW, Secretary.
Office—Room 69 Nevada Block, No. 309 Montgomery street, San Francisco, California.

DELINQUENT SALE NOTICE.

STANDARD GOLD AND SILVER MINING CGM Sany. Location of principal place of business, San Francisco, California. Location of works, Butte County, California.

Notice—There are delinquent upon the following described stock, on account of Assessment (No. 1) levied on the 18th day of December, 1893, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No.	Shares.	Am't.
E. McGrath.....	32	500	\$85 00
E. McGrath.....	34	500	25 00
E. McGrath.....	35	500	25 00
Sylvester Gardner, Trustee.....	40	1,000	50 00
Sylvester Gardner, Trustee.....	62	200	10 00
Sylvester Gardner, Trustee.....	63	1,000	50 00
Sylvester Gardner, Trustee.....	68	1,000	50 00
Sylvester Gardner, Trustee.....	69	500	25 00
Sylvester Gardner, Trustee.....	69	3,750	187 50
Sylvester Gardner, Trustee.....	74	2,000	100 00
Sylvester Gardner, Trustee.....	75	2,000	100 00
Sylvester Gardner, Trustee.....	78	16,675	833 75
Sylvester Gardner, Trustee.....	82	1,000	50 00
Sylvester Gardner, Trustee.....	100	9,490	474 50
Sylvester Gardner, Trustee.....	101	10,000	500 00
Sylvester Gardner, Trustee.....	103	10,000	500 00
Sylvester Gardner, Trustee.....	104	2,065	103 25

And in accordance with law, and an order of the Board of Directors, made on the 18th day of December, 1893, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the Company, 330 Pine St., Room 4, San Francisco, Cal., on SATURDAY, the 17th day of February, 1894, at the hour of 1 o'clock P. M. of said day, to pay said delinquent Assessment thereon, together with costs of advertising and expenses of sale.

T. E. JEWELL, Secretary.
Office, 330 Pine Street, Room 4, San Francisco, Cal.

The Case Engines.

New varieties of the Case automatic high-speed engine for small powers have been received here by the Parke & Lacy Co., the agents, and are deemed worthy of illustration.

The Case Company manufactures three main varieties, all embodying the same principles, viz., the pedestal engine, which may be bolted to a substantial floor or to a foundation; the bracket engine, to be fastened directly on the wall where floor space is difficult to obtain; and the hanger engine, to be bolted to an overhead beam; also sundry varieties for special kinds of work, such as driving fans and exhausters, hoisting elevators, etc.

The transparent cut shows that the piston is connected directly to the crank-pin without the intervention of a connecting rod. The piston connected thus at one end to the crank-pin direct travels back and forth at its other extremity through the bore of the cylinder. The latter, by reason of its shape, is free to turn in its casing and is therefore rocked by the vibrating piston rod through an arc sufficient to open and close steam and exhaust ports on its face. The perfect steam balancing of the cylinder permits this rocking motion without friction. A long sleeve screwed into and forming an integral part of the cylinder, and through which the piston rod works, imparts the rocking motion to the cylinder.

The upper end of the cylinder is open, so that steam ad-

AUTOMATIC BRACKET.

As to regulation, the governor differs from the common type of shaft cut-off governors, inasmuch as it does not diminish the throw of the valve and so throttle the steam on light loads, but has always the same amount of travel, the regulation being effected by its rotating the eccentric on the shaft, and thus giving the valve the right amount of lead over the crank.

The cut-off valve is of the plug type, made with a slight taper so that it can always be kept tight. Its only duty is to define the point of cut-off, the admission, release and exhaust closure being controlled by the rocking of the cylinder which forms a valve action.

The lower half of the case forms a reservoir for oil and water, into which the crank-pin dips at each revolution. The lubricant is conveyed to the bearings at every stroke automatically by pockets in the crank-discs. After the oil has done its work on the bearings, it returns to the case again by gravitation. Any excess, which would naturally work out on the shaft, is thrown off by centrifugal action, from ring wipers, and returned by a separate passage to the case; thus the same lubricant is used over and over again. The oil and water finds its way through small openings to a settling chamber below the reservoir; and, being away from the churning action of the crank, the oil separates from the water and returns to the upper case. A stand-pipe is connected with the bottom of the settling chamber, and consequently the overflow itself is always water. The cylinder is lubricated by an efficient sight

AUTOMATIC PEDESTAL.

WORKING PARTS.

THE CASE AUTOMATIC HIGH SPEED ENGINE FOR SMALL POWERS.

mitted for the downward stroke sets from the head of the piston to the face of the surrounding casing or steam chest, and there is consequently no steam thrust that would tend to cause friction of the cylinder against the casing.

The lower end of the cylinder is closed, but the same

thing is accomplished for the upward stroke by the admission (through passages leading from the ports) of a thin film or layer of steam to a small balancing chamber, of equal area with the piston, hollowed out in the bottom of the cylinder. By this method no power is required to rock the cylinder, it being steam-balanced and frictionless.

feed oiler, furnished with each engine, to be connected to the steam pipe.

The bracket and hanger engines are novel varieties and make possible the use of an engine (directly coupled or belted to its work) in locations where no other engine could be placed, and in many cases save valuable floor space.

In view of the tremendous depreciation in silver and lead values the semi-annual report of the Broken Hill Proprietary Company, New South Wales, is full of interest. The six months' production was over 6,500,000 ounces of silver, making the total for one year ending Nov. 30, 1893, 12,500,000 ounces. The Australian record was thus broken. To be exact, the output has increased during the half year from 5,894,962 ounces silver and 21,690 tons lead, to 6,533,232 ounces silver and 25,822 tons of lead. The ore treated rose from 208,042 tons to 246,520 tons, but the average output shrank from 28.34 ounces of silver per ton to 26.5 ounces per ton, though the yield of lead is almost unaltered. If to the above output is added the tailings, etc., treated, it brings the total of ore dealt with to 260,047 tons. The cost of winning the silver and lead from the ore was £2 13s 10d per ton, and as the value of the ore was £4 8s 9d per ton, there has been a net profit of £1 14s 11d per ton. Here, again, there has been a shrinkage in the worth of the ore from £4 16s to £4 8s 9d, but this is largely due to the utilization of the lower grade materials and the conservation of the carbonates. It would be interesting to know the value on which the calculation as to value is based. The result of all these operations has been that during the half year the shareholders have received £283,000 in dividends and £30,000 in bonuses; £30,065 have been allowed for depreciation, and £40,024 have gone into construction account. The total expenses during the half year have absorbed £700,061 out of the total of mine earnings of £1,154,294. Out of the net profits of £453,633, the directors have not only paid dividends, etc., but have put £30,000 to the credit of the reserve fund, which now stands at the respectable total of £110,000.

THE controversy between Mr. Chapman and Mr. McLeod is really no controversy at all. Each gentleman practically agrees with all the other says, though perhaps not with the manner of statement. Mr. Chapman advocates deep mining, but it does not follow that he is not favorable to surface mining. Mr. McLeod advocates surface mining, but he is by no means opposed to deep mining. Mr. Chapman's position is substantially that the absence of pay ore near the grass roots, if other indications are favorable, is no indication that the mines will not pay at a reasonable depth. Mr. McLeod's position is that surface mines have contributed the greater part of the wealth of the country, and will continue to do so. Mr. Chapman thinks a mill should not be erected until the mine is more than a hole in the ground. Mr. McLeod agrees with him; but he does not think it necessary to wait until the sinking has reached the 1000 level before erecting a mill. He is right.

THE Moser mine has been shut down in Calaveras Co. owing to differences between the lessees and owner, S. S. Moser. It is hoped, however, that arrangements now pending will be made to reopen the mine in a few weeks.

A Harmful Decision.

A press dispatch from Washington, under date of February 17th, contains the following:

The practice of the General Land Office has been materially changed by the Secretary of the Interior in the case of E. O. Farrell et al. against William L. Hoget et al. of the Helena, Mont., land district on appeal from the decision of the Land Commissioner. The Secretary holds that the holder of each 20-acre tract of any placer claim must show discovery of minerals in order to obtain a mineral patent. Whether the claim is surveyed or unsurveyed makes no difference in the rights of the locators. Accordingly, location made on a larger amount of land is void, except for the 20 acres immediately surrounding it. This is a reversal of the action of the Land Office.

If the Secretary of the Interior is correctly reported, he has rendered a decision most seriously menacing the interests of every State and Territory containing auriferous gravels. It is well known that the practice is, or has been, in this State to locate claims to be worked by the hydraulic process, to the extent of 160 acres, the full limit allowed by law. These claims are located by associations, each individual representing 20 acres, or less, the organization being effected that the gravel beds might be systematically and economically worked. It has been heretofore held that the presence of gold in one of the tracts covered the entire location of 160 acres. The entire reasonableness and the necessity of this construction of law are apparent to all who know the meanderings of the old river beds in which the gold occurs and the difficulty of establishing the presence of gold in any particular spot in the gravel by mere prospecting. That is to say, when it is desired to mine gravel on the scale usually practiced in California, the territory must be sufficient; and 160 acres are often little enough. Under this decision only 20 acres at a time can be located, unless the presence of mineral is established in all the subdivisions desired to be embraced in 160 acres. The meanderings of the auriferous channel must therefore be determined in advance. It cannot be done.

The decision is ruinous to the prospective hydraulic mining enterprises; and we assume that it will affect present unpatented holdings in each subdivision of which the presence of mineral has not been established. It is but another instance of the steady trend of decisions against mining interests by the higher officers of the government, and well illustrates the increasing difficulties with which efforts to obtain mineral lands are surrounded. It emphasizes, also, the very great need of a clear, fair and unambiguous code of mining laws, which shall protect the interest of the miner as well as the government and the general public. The bill of the California State Miners' Association, just introduced in the House by Congressman Newlands of Nevada, is a step in the right direction. Among other reforms, it will correct the particular grievance inflicted by the decision of the Secretary. It provides that where a claim is in a well-known mineral belt it shall be presumed to be mineral; and so shall the adjoining territory. It is to be hoped that Congressman Newlands, in his efforts to secure the passage of this highly necessary measure, will have the earnest support of delegations from all the mining States.

The Moffit Process.

THE PRESS recently contained a brief notice of the Moffit process of base ore reduction, the invention of Mr. J. R. Moffit of Stockton. The process has attracted some attention, and additional particulars may be of interest.

The inventor claims to have expended over \$30,000 in his various experiments. He is a Massachusetts man and came to California about 12 years ago. He took his first patent out in 1885, and a patent for an improvement thereon in 1890. Since that time he has applied for two additional patents. He has also many other claims covering the same system. The machinery occupies very little space and is constructed so that it can be easily transported over mountain roads.

The three conspicuous claims of the invention are: First, the application of incandescent heat with cyclone motion; secondly, the separation of the gases under atmospheric pressure; and thirdly, the precipitation of the precious metals, liberated from all refractory elements.

IT IS ANTICIPATED that the State Anti-Debris Association may not in future have the strong backing from the various county governments it has had in the past. At the last meeting of the Sacramento Board of Supervisors Chairman Morrison said: "Now, gentlemen, here is a bill in regard to which I was called before the Grand Jury. It is for our monthly dues to the Anti-Debris Association, \$300. The Colusa Grand Jury recommended that that county double its subscription, but I don't know what our Grand Jury will do. This bill we owe already, the only question being as to the future." Supervisors Ourtiss and Todd expressed some doubt as to the advisability of maintaining this expense, but the members of the Board were

unanimous as to the allowance of claims already accrued. The demand was ordered paid and the subject was not further discussed. It seems to be a fact that the Anti-Debris Association is not giving the river counties value received for the appropriations from the Supervisors. There is now no real controversy between miners and farmers, and the maintenance of the organization is useless.

Miners' Strike at Cripple Creek.

A strike of miners at Cripple Creek, Colo., has resulted in the closing down of all the leading producers in that camp. The trouble arose over the attempted enforcement of the eight-hour law by the Micoers' Union. The mine owners gave notice that they would demand nine instead of eight-hour shifts after February 1st, at the same wages, and the Miners' Union refused to accede to the demand. Posters were sent out by the union warning miners to keep away from Cripple Creek. The mine manager who is accused of having started the move to increase the hours was caught, while accompanied by two armed body guards, the three disarmed and the manager forced to get down on his knees and swear that he would leave the camp and never return. A dozen men have been arrested, charged with being the leaders of this attempt at mob rule.

On February 7th 200 miners met on Bull hill and proceeded to the various mines still working the nine-hour shifts and demanded that they adopt the eight-hour schedule or close up. They succeeded in placing the North Star, Gold Dollar, Prince Albert, Climax, Kismet and Santa Rita on the list of eight-hour mines. The Granite was closed up because the foreman refused to permit the men to work eight hours. Of course the superintendents of the mines agreed to the demands of the men through fear of mob rule, and probably with no expectation of carrying out their agreement indefinitely.

A few days later a meeting of Cripple Creek mine owners was held. Nearly all the large mines were represented. The meeting was a secret one, but it is learned from an authoritative source that the owners decided to adhere to their demand for a nine-hour day at the rate of \$3, and to keep the mines closed until this was accomplished. The owners present represented mines employing over 500 men.

The miners appear so far to have the best of the situation; but it seems likely that they will be worsted in the long run. The number of unemployed miners in Colorado is very large, and they will not be disposed to stand on ceremony in taking the places of the striking miners. Of course there is some fear of violence if they attempt it, but starvation is a more powerful persuader than fear of personal injury.

It is reported that the non-union miners of Colorado are already on their way to Cripple Creek from the various camps of the State. They have been assured that they will be protected in taking the strikers' places. The end of the strike seems not far off.

Boring for Gravel Mines.

Important results are announced to have followed prospecting for gravel ground on the Forest Hill divide; and the utility of boring machines for that purpose has been very satisfactorily proved.

President Chappelle of the Mayflower Drift Mining Company, some months since bought a boring outfit for \$1,400. Five or six holes have been put down to varying depths and some valuable developments have been made. By means of these borings at least two new and heretofore unknown gravel channels have been discovered, one of which is supposed to be a continuation of the famous channel on which is located the Paragon mine at Bath. The other is on the Mayflower, and immediately over the channel which the company is now working. The present works are 614 feet below the surface. In boring through to the present works, at a depth of 452 feet the auger cut through a channel of reddish gravel about eight feet in depth, the existence of which was never suspected. Again, at a depth of 590 feet from the surface, another channel, heretofore unknown, of blue gravel, and about seven feet in thickness, was cut through.

These discoveries the *Placer Herald* considers very important. The gravel from them prospects well and the possibilities of their future development may be very great. Whatever comes of them may be credited to boring, for it is more than likely that except for the institution of the process as an element of mining they never would have been known.

THERE are indications of a very active season of gold mining in Tuolumne county. The great success of the Rawhide has attracted attention, and has done much to advertise the merits of Tuolumne's mines. Several important mining deals are on the tapis, and there is no doubt that some, or all, of them will come to a satisfactory conclusion.

The Necessity of Full Development.

By W. S. Chapman.

I am glad to see that my remarks on gold mining in California have called out the very intelligent and just criticism of Mr. Taylor D. McLeod. He evidently knows whereof he writes, and his views upon the subject of deep mining I fully and unhesitatingly endorse.

Very many rich mines of this State have paid from the surface down to a greater or less depth; and when good pay ore is found in any mine in quantities to justify the erection of mill and hoisting works, no one would object to the proper utilization of the treasure. The less depth of such results the more cheaply it may be worked, of course.

When large, well-defined veins of mineralized ores are found, but of too low grade to justify the erection of expensive works, it surely should not be abandoned and declared worthless short of a thousand feet in depth, or even much more. The Kennedy mine was abandoned at about 600 feet in depth, as have been very many others on the same great lode. The Utica was also abandoned because it was too poor to pay for exploration, and even now while paying more than any other mine in this State, it is yet only 900 feet deep. This instance shows clearly the importance of thorough prospecting to a considerable depth before abandoning a mine as worthless.

Sinking a shaft in poor ore does not by any means prove the mine to be worthless. It is well known that rich ore is found in chutes and not always equally distributed throughout the entire length and width of the vein; hence the imperative necessity of drifting some distance upon the vein in order to satisfy the miner of the real merits or demerits of the mine.

It is entirely possible to sink a shaft to a considerable depth in ore of very little value, while a very valuable pay chute may be within reach of a drill, as very pertinently suggested by Mr. McLeod.

This suggests to my mind the importance, in all the large mines, of the more frequent use of the diamond drill. I am satisfied that in many instances large bodies of good ore have been left undiscovered where a good drill would have developed the hidden treasure at a mere nominal cost of time and money, while to extend a drift for the same purpose would be costly, and in many instances the uncertainty and cost forbid the test.

One notable instance recurs to my mind where this condition existed in a most marked degree. At Tombstone, in its best days, I went very thoroughly through one of the leading mines with Mr. James, then in charge, and he showed me a drift which he had run, as I now remember, over 100 feet, following a small white line, not larger nor unlike a chalk line. The line was only visible when shown to me on the top of the tunnel, but it led to a body of ore from which he extracted more than a million dollars' worth of ore. There was, so far as he could find, no clue to that valuable ore deposit, save alone this apparent chalk line. A diamond drill would have reached that ore body in a few days, at a very small cost. But for the observance of that small line, followed more out of curiosity than anything else, that ore would have been left, possibly, for the next generation.

What California wants is capital to develop her mines, and confidence to engage in that enterprise as a business, and that confidence can only result from intelligent, faithful management.

W. S. CHAPMAN.

Miners' Boarding-House Blown Up.

At 3 o'clock Monday morning a tremendous explosion aroused the whole camp at Angels, Calaveras county. It was thought at the time that some of the powder-houses at the mines had blown up, and that a great quantity of explosive had been ignited. The report was so loud that it was heard at Murphys, six miles away, and so violent that most of the window glass in Angels was shattered.

It was found after an investigation that for the second time recently a house had been blown up by the use of giant powder. The house destroyed this time stood just across the street from the Sticks hoisting works, and it was owned and occupied as a boarding and lodging-house for the miners by an Austrian named Mitchell Magud. The building was known locally as the "Old Dick Hockman House." It was sold to the Austrian about a year ago. It contained some five or six rooms.

At the time of the explosion the miners were all at work on the night shift in the mine, and as far as can be learned the only persons in the house were Magud, his wife and their two-year old child. The giant powder was placed outside on the steps leading down to the basement, and when it exploded the house was literally blown into kindling wood. By what must be considered as almost a miracle the lives of the three persons in the building were

saved. When the walls of the house went out the roof fell and imprisoned Magud and his wife, who were thus protected from the falling timbers. The baby went through a hole in the floor and dropped into a wine tank below, being unharmed by the fall. The doctor who was at once summoned, found that Magud had been bruised about the ribs, and Mrs. Magud scratched on the neck. Otherwise they were not hurt. Pieces of the timber from the house fell a block away, and all the windows in the houses near by were left without glass. It is thought that 20 pounds of powder were used. The police here are working on the case, but can only conclude that the man who blew up this house may be the same who blew up the other something over a year ago. It is surmised that it may be the work of a crazy man, which makes the citizens very apprehensive.

Many Resolutions Passed.

The Trans-Mississippi Congress concluded a very busy and notable session in this city last week, having discussed a great variety of subjects. It passed the hydraulic mining and river improvement resolutions (published in last week's issue) and adopted also the following:

Resolved, That we recommend the opening of the mints to the coinage of silver on the same terms that they are now opened to the coinage of gold, and at the ratio of 16 to 1.

One of the most important resolutions of the session, introduced by Governor Rickards of Montana, was considered on its merits and received unanimous approval. It is as follows:

Resolved, That Congress is hereby memorialized to take such action as will insure to the people the mineral lands lying within the limits of the land grants heretofore made to railroads, and so legislate upon the subject that no mineral lands shall pass under said grants.

Resolutions recommended by the committee were read by the secretary as follows and adopted with but few dissenting voices: Requesting the erection of defensive works for the protection of the Pacific coast and Puget Sound; asking that all mountain forest lands be saved from mountain fires and the same be preserved for their bearing upon the irrigation problem; that an experiment station be established in the center of the arid belt country; providing for the admission into the Union of New Mexico, Utah and Arizona; suggesting that Senators and Representatives be asked to present the resolutions of the congress, and that they act in concert; that a national bankruptcy law be enacted; condemning the policy of forcing upon Hawaii a restoration of the monarchy as abhorrent to justice and to the principles of the American people, prohibiting the dominance over the islands of any foreign power, and favoring the peaceful annexation of the islands as the true solution of the Hawaiian problem; urging the laying of a submarine cable to the Hawaiian Islands; recommending the creation of a Secretary of Mines and Mining as a member of the President's Cabinet; demanding the immediate opening to settlers of all Indian lands ready for settlement; recommending the establishment of a postal telegraph and postal savings banks; demanding the foreclosure of the Central Pacific mortgage when the same shall become due; urging the improvement of Coos Bay harbor and the fortification of San Diego harbor; urging the improvement of the Willamette river so as to render it navigable to Eugene City; asking Congress to provide for the selection of United States Senators by direct vote of the people instead of by the indirect vote through Legislatures; and endorsing female suffrage.

Slickens.

The Good Hope mine, near Ferris, is to start up at once.

The Bald Butte Mining Company of Montana recently paid a dividend of five per cent, amounting to \$12,500.

The Rico-Aspen Consolidated Mining Company of Colorado has paid a dividend of 2½ cents per share, amounting to \$25,000.

The Standard Consolidated Mining Company of Bodie District has declared a dividend of ten cents per share, aggregating \$10,000, and payable March 15th.

The Homestake Mining Company of South Dakota has declared a dividend of 10 cents per share, amounting to \$12,500 payable February 25th.

The Oroville Mercury advocates the construction of a good road from Oroville to Forbestown, on the ground that the latter has now become a leading mining center.

JOHN K. BALWIN, a young farmer on the Calaveras river, has found a ledge of disintegrated, high-grade quartz on his place near Bear mountain. He will now become a miner.

Plans and specifications have been prepared for a 20-stamp mill on the Dividend mine, Prescott, Ariz., and the company have invited bids for its erection. They expect to have it in operation within 90 days.

A WONDERFULLY rich gold find has been made in the Colorado desert, sixty miles from San Bernardino and twenty miles from Indio. Old miners think this discovery is where the Indians used to find the gold they showed to people in Caliente.

A CENTENARIAN died a few days ago on the Mission road near San Diego. He was a pioneer miner named D. Burchard, and he had reached the great age of 103 years and five months. He was a native of New York and had been in California 43 years.

THURSDAY EVENING a timberman at the Standard mine at Burks, Mont., named John Sullivan lost his footing and fell about 120 feet. Upon examination it was discovered that no serious injuries beyond the fracture of one arm were received by him.

EXCITEMENT prevails in the vicinity of Needles over the new gold fields in the vicinity of Goldstone, about twenty miles west of Fenner. Miners are flocking there from all parts of the country. Assays from five claims show very well. The mountains are well supplied with wood and water.

The Bullion Consolidated Company has filed articles of incorporation. Principal places of business, Forbestown, Butte county. Capital stock, \$70,000, with Charles Bonvier, Bannett

Moyle, George Albert, Frank Willst, Jesse Clement, John Peller and William Smitherton of Forbestown as directors.

A SMALL EXCITEMENT has been stirred up in Oakland by the finding of a gold nugget in a bluff on the east shore of Lake Merritt. It does not indicate a gold mine by any means. Nuggets have been found in that vicinity at rare intervals, but they seemed to have strayed a long distance from home.

It is stated on good authority that T. R. Hofer, Superintendent of the United States Mint at Carson, has received notice from Washington that his resignation would be accepted. Ex-Governor Adams, Milt Elstner, Harry Day, J. C. Haggerman and John Wagner are mentioned as probable successors.

A DEPUTY UNITED STATES MARSHAL from Portland levied an attachment upon the Hammersly mine in Josephine county, Or., to satisfy a judgment in favor of the Government for \$16,000 against the Hammerslys, father and sons, for cutting timber on government lands in eastern Oregon several years ago.

OCEOLA Consolidated Gold Mining Company has filed articles of incorporation. Principal places of business, San Francisco. Capital stock, \$100,000, with Frank D. Monckton and Sheldon P. Monckton of San Francisco, John C. Franks and Carrie A. Franks of Alameda and John L. Ashley of Fresno as directors.

The South Spring Hill mine, Amador county, after shutting down temporarily, is soon to start up. The shaft is being repaired at present and the intention now is to sink a new shaft and prospect the lower levels below the 900-foot, which will undoubtedly prove the mine to be valuable property, and place it again upon the list of dividend-paying propositions.

At the annual meeting of the Standard Consolidated Mining Company the old management was unanimously re-elected. The directors are: Thomas H. Leggett (president and general manager), William Burrows (acting president), J. W. Pew (secretary), W. H. Oscanyan, C. H. Badeau, A. P. Bratton and John Mason. The company has in its treasury the sum of \$41,685.57.

THE COMPANIES owing furnaces at Denver have decided to shut down half of their furnaces. This action was made necessary on account of inability to get ore stocks or carbonates. The recent development of gold properties and the consequent unusual amount of gold ores to be handled largely increased the demand for carbonates. The supply is short by reason of the shutting down of so many lead-silver mines.

A CORRESPONDENT of a Butte paper, writing from Basin, says there is no need of booming that camp, as people are going in there too fast to be accommodated already. The hotels and lodging houses are so crowded every night that there are not rooms enough to go round. The snow is quite deep and there is no work except in the mines now operating. There are no peace officers in the camp and the residents are going to petition the County Commissioners to make some appointments.

THE sulphurets from quartz mines in Siskiyou county, if saved and properly worked, will pay handsomely, says the Yreka Journal. In fact, very few mines yield good returns without gaining the gold in the sulphurets. If they are reduced down to a high grade and shipped below to the Selby works there is no doubt about the certainty of realizing handsomely. Those interested in quartz mines will do well to investigate this matter and save up the sulphurets for shipment in carload lots.

THE gold mines of southern and eastern Oregon are going to be factors of no small moment in the revival and support of business in Oregon. The Oregonian says that they will yield \$2,000,000 this year and probably more. Whatever they produce is so much new money brought into existence for payment of labor and support of trade. More attention will now be paid to Oregon's mines than at any time during the past 25 years. Low value of wheat, wool, lumber and other products are sending much labor back to gold mining.

SHIPMENTS of Mexican dollars to China go by every outgoing steamer. The silver bullion in bars and bricks sent out is unusually considerable. The Peru took for Hongkong banks last week \$142,000 in Mexican dollars, \$151,000 worth of bar silver, \$1395 in gold coin and 4600 Peruvian soles. Silver is the principal circulating medium in China, as it is in Japan, India and other oriental countries. By the Peru there was also shipped \$39,000 in bar silver to Japanese banks in Yokohama and Tokio. The total shipment by the steamer was \$338,059. Nearly every steamer sailing from here to the Orient takes \$200,000 to \$400,000 in specie.

A SUMMARY of the operations of the British Mint during 1893 has just been issued by the authorities. It shows that the total amount issued in gold was £8,915,751, and the sum withdrawn (under the provisions of the Coinage Act, 1891) £6,300,000, as compared with £13,697,540 and £16,200,000 respectively in the previous year. During 1892 light gold coin of the value of £1,163,125 was also received as bullion. The silver issued in 1893 represented £1,008,971, as against £849,932, while the total amount withdrawn was £294,113, compared with £227,216 in 1892. The total sum issued in bronze during the period under review was £46,664; in the previous year it was £58,556. The amount of silver bullion purchased was 2,212,303 ounces (troy), valued at £334,587. The average price in London market was 35½d. per ounce, as against 39 13-16d. in 1892. The total number of coins struck at the Mint during the past twelve months was 78,094,480, as compared with 67,334,847 in the preceding year.

THE smelter of the Puget Sound Reduction Company at Everett, Wash., started its fires last week and will make a test run with the ore on hand, which is sufficient to carry one furnace about two weeks. Base bullion will be turned out there and sent to San Francisco to be refined. Silver predominates over other precious metals in most of the ore now in the bins, though there is considerable gold in some of the rock. There is a large percentage of lead, to be sure, with some copper. The concentrator at Monte Cristo is now practically completed, and only the spouts and chutes for handling ore yet remain to be constructed. The machinery has all been in place for several days, and a satisfactory trial run was made last week. It is the opinion that the Everett smelter will treat concentrates from Monte Cristo early in March.

Mines and Mining in Nevada County.

TO THE EDITOR:—Since my last correspondence to the PRESS two transactions of exceptional importance have been consummated in this district. I refer to the transfer of the Idaho mine to the Maryland Company, and also the purchase by Mr. Hague of the Rocky Bar, Stockbridge, Great Britain, New York Hill and Massachusetts Hill mines. These transactions are full of significance to this city, and indicate an era of great prosperity in the near future. It is very fortunate for this community that the Maryland Company has complete control of the Idaho property, for they can now continue developments without the obstruction or restriction of any outside influence. It is very advantageous to be thus unincumbered, and it is hoped that at no distant date the full complement of men will be employed at the Maryland mine. Mr. Dorsey, the president of the Maryland Company, has announced his determination to push operations with energy and vigor, and the necessary buildings are being constructed with great rapidity.

It is almost impossible to estimate the effect which the reopening of this mine will have on this district. Not only will it give employment to a large number of men who are now idle, putting a large revenue into circulation every month, but it will prove how far the Idaho vein runs into the Maryland property. The fact that all the operations will be conducted in the Maryland mine will prove the extent and richness of that property. The successful operation of the mine will stimulate others to develop properties situated in that locality.

Mr. Hague, purchaser of the mines above referred to, is the president of the famous North Star mine of this city, and through the personal attention paid to this mine by him it has been developed in a highly successful manner. In the mining world he is regarded as a shrewd and careful speculator, and his previous investments in this district substantiate this assertion. The rehabilitation and development of these old abandoned properties will be watched with interest by the mining world. Mr. Hague's connection with them will give them prominence and reputation among mining men; and that he is in a position to place a proper estimate upon their value no one will dispute. The section in which these mines are located was at one time the most productive and prosperous environment of this city, and there is no apparent reason why the circumstance should not be repeated. The mines, without exception have only been developed to a superficial depth, and in the aggregate they have produced millions of dollars. These mines were never abandoned because of any depreciation in their intrinsic value. Rich ore veins are known to exist in this locality, and they have never yet given evidence of diminishing in size or value. The old Rocky Bar mine has produced approximately \$2,000,000, and the New York Hill claims the credit of producing over \$1,200,000.

The future of Grass Valley is bright indeed, and with cheaper and increased motor power we shall in a few years double our present production.

Very few people seem to know that gravel of any value or quantity exists in this city. Yet there is a rich gravel channel which runs through the heart of the city, and which has been traced to You Bet, ten miles to the east. In the early days this channel was worked extensively, and at places it was found to be extremely rich. At one place—under the site where our present high school is situated—a layer of gold was found, three-quarters of an inch in thickness. But on account of the channel being small and the gravel being strongly cemented the process of extraction was tedious and extremely slow. But many thousands of dollars were extracted by many men who are to-day residents of this city. Most of the work on this channel has been done in the vicinity of Alta hill, a mile north of town. In 1870 over a dozen companies were engaged in gravel mining on this hill. The channel was worked successfully and over \$500,000 was produced, and the "lead" was lost and work was abandoned. For the past eight months the Jenny Lind Gravel Company has been operating on this hill. They ran a tunnel east into the hill 500 feet. The roof of the tunnel is 265 feet from the summit of the hill. A short time ago while putting an upraise to the surface for the purpose of ventilating the mine the old "blue lead" was intersected eighteen feet above the roof of the tunnel. This is the "lead" that was lost in the Hope mine a number of years ago. It is dipping east and displays a thickness of four feet. The company, which is composed of workmen, is very jubilant and anticipate important developments in the future. The claim has an area of 120 acres.

Exit Idaho. With the transfer of the Idaho property to the Maryland company the name of "Idaho" will be dropped from the annals of mining and will only be known to us as something that existed in the past. It may not be

inappropriate at this juncture to give the readers of the PRESS a brief history of this famous mine.

The mine is situated about a mile and a half east of the city of Grass Valley. It was discovered in the bed of Wolf creek, in the early days of placer mining, and located May 9, 1863, by a number of citizens, prominent among them being the Coleman brothers, M. P. O'Connor, A. B. Dibble, Peter Johnson, Jules Fricot, F. G. Beatty, S. W. Maslin, William Loutzenheiser, A. B. Brady and Geo. D. McLean. Scant attention was paid to the claim for a number of years, only the necessary assessment work being done to prevent the mine from being "jumped" by outsiders. The quartz taken from the vein during these annual workings was of a very low grade; the vein was small, and no effort was made to develop the mine systematically until the summer of 1865. In the summer of that year work was commenced in the creek, with the intention of following the croppings as far as possible, but in this the owners were disappointed, as the croppings could not be traced more than 175 feet from the western boundary of the company's claim. The quartz seemed to be very poor, showing no gold and carrying but very little sulphurets, but it gave signs of permanency, and the company decided to prospect. A prospecting shaft was commenced, and as depth was attained the ledge began to improve in size and appearance, and the owners determined to erect machinery and develop the property on a large scale. A twelve-inch pumping engine and an eight-inch hoisting engine were erected, and on the 5th day of July, 1865, a vertical shaft was commenced on the south side of the creek, about 290 feet from the western boundary. This shaft was located so as to intersect the ledge at a depth of 150 feet.

At a depth of 120 feet from the surface a ledge was encountered, but as it was small and not bearing any gold or sulphurets, it was rejected as being of no value. About this time the company became financially embarrassed and it was decided to suspend operations. In 1867 a more complete organization was effected by the incorporation of a company under the name of the "Idaho Quartz Mining Company," with a capital stock of \$310,000, divided into 3100 shares, each share representing one foot of the ledge. Work was shortly after commenced by sinking the shaft still deeper. One hundred and forty feet from the surface the fissure was struck, but there was no quartz, there being a few inches of clay formation where the ledge should have been. The shaft was continued to a depth of 300 feet from the surface, without meeting with any success. At this juncture a drift was run west and 108 feet from the shaft the ledge was intersected, showing gold quite freely, the first twenty carloads paying \$29 per load. This marked the beginning of the era of prosperity enjoyed by this company. After a few months of exploration work it was decided to erect a fifteen-stamp mill. The erection of the mill commenced in the summer of 1868, and was completed and put to work in October of the same year.

At the annual meeting held on the second Monday in December, 1868, the superintendent's report stated that the expenditures for the previous 15 months, or since the incorporation of the company, had been \$68,098.63. It may be interesting to note that the money expended by the stockholders for the development of the mine and placing it on a dividend-paying basis was, from the commencement of work in 1865 to the incorporation of the company, the sum of \$19,490.50, and since the incorporation, \$19,053.25, the whole aggregating \$38,543.75. After striking the ledge in the 300-foot level the shaft was continued down, but no quartz was encountered until a depth of 520 feet from the surface was reached. At this point the ledge formed, and the shaft was continued to the 600-foot level, where drifts were run both east and west. Explorations were continued, and each month added to the value and permanency of the property, and it soon became recognized as the leading quartz mine of the State.

In 1871 a new shaft was commenced about 150 feet east of the old one. This shaft was 6x20 feet within timbers and supplied with cages and all the other modern appliances. In 1872 hoisting engines of the most approved character were placed on this shaft, and they continued working without interruption until the great fire of a few weeks ago. The mill was enlarged by the addition of 20 stamps, making 35 in all. The improvements made in that year incurred the expenditure of \$102,222.52, and, in addition to this large outlay, the yield from the mine, with 15 stamps crushing, gave the company a surplus of \$162,750 for the year, after paying all the necessary expenses.

The Idaho is an east and west vein. It has been one of the most valuable in the State, having yielded pay ore for a distance of 1600 feet along the level. Its foot wall is a serpentine rock and its hanging wall a metamorphic. The size of the ledge has varied from one to six feet, giving an

average thickness of from three to four feet. The quartz has paid regularly, as may be inferred from the fact that for a period of 135 months, commencing in 1869 when the first dividend was declared, 127 monthly dividends were paid, leaving only eight months in eleven years without a dividend. The gross output of the mine to May, 1893, was \$11,864,822.14. Paid in dividends to May, 1893, \$5,035,950, making the total number of dividends up to that date 275. Since May 1, 1893, the mine has been under the control of the Maryland Company, and over \$70,000 of the purchase price has been paid to the Idaho Company. This money has been extracted from the Maryland property, and there is every reason to believe that this mine will develop into as rich a property as its famous predecessor.

Grass Valley, Feb. 20, 1894.

SAMUEL BUTLER.

The Greatest Mine in the World.

The report of the general manager for the half-year ending November 30, 1893, shows that the output of the Broken Hill Proprietary Company's mine, New South Wales, exceeded all previous records. During the half-year there were treated 260,047 tons of ore, showing an extract of about 10 per cent of lead and 25 ounces of silver per ton, and producing 333 tons of copper (in matte), 25,822 tons of lead, 1431 ounces of gold and 6,533,232 ounces of silver, as is shown by the subjoined statement.

PROCESS OF TREATMENT.	Ore Treated	Copper Matte.	PRODUCT.

Rapid Shaft Sinking.

A recent discussion in relation to rapid shaft sinking on the Comstock lode led the *Territorial Enterprise* to the collection of the following statistics:

The Savage, Norcross and Chollar joint shaft, known as the Combination, has four full-sized compartments, each six feet in length by four feet in width, requiring an excavation nearly forty feet in length by seven in width to allow room for timbering. This shaft was sunk to a depth of more than 2500 feet, and closely timbered with 12x14-inch timbers, in two years, and several working stations were opened at the same time—each capacious enough for a dance-hall.

The joint Best & Belcher and Gould & Curry shaft, known as the Osbiston, was sunk to a depth of 2000 feet below the surface in 18 months. This shaft has three compartments. Both of the above shafts were sunk through a diorite formation, requiring heavy blasting for almost every foot attained in depth. A record of 110 feet a month has frequently been made by Comstock mining companies in sinking.

For rapid drift driving the Comstock has never been excelled. On the 3100 level of the Combination shaft a south drift was advanced 115 feet in one week, and this with a cloud of steam arising from the water in the sump showing a temperature of 120 degrees; meanwhile the ponderous hydraulic pumps were lifting to the Sutro tunnel level nearly 4,000,000 gallons of this steaming water every 24 hours. The speed of driving the Chollar drift is said to have been excelled in several instances, but that in the Chollar is the longest drift ever run on the Comstock at that depth below the surface.

THE Providence Mining Company, at Nevada City, is about to increase the capacity of its mill by the addition of ten more stamps, making 50 in all. The Providence will then have the largest mill in Nevada county. Under the efficient superintendence of Col. Davis it has developed into a most important property, and will doubtless continue to be a large producer for years to come. It has not been so very long ago—two or three years—since the Providence was a "worked-out" mine. There are many other such in California.

A Reply to W. S. Chapman.

By Samuel Butler.

I desire to utilize the columns of the PRESS in the interest of a class of men of which I am a unit, and for the purpose of debating certain statements of a correspondent which appeared in your issue of the 10th inst. I refer to an article under the caption of "Needed Changes in Mining Methods," from the pen of W. S. Chapman.

While there is little in the article to arouse the interest or excite the sympathy of miners in general, there is much to arouse the indignation and incur the enmity of the class of people against which it was principally directed. That the expressions will be condemned by working miners and also by mine-owners is a foregone conclusion.

In thus taking issue with this writer on an important question, it may be inferred by some that I am biased in my statements, arising from the fact of my following the avocation of a miner. But this fact shall not be permitted to prejudice my mind against the assertions made by Mr. Chapman to which I take strong exception.

In making what he evidently considers a strong plea for the more economical development of our mines, he remarks: "There is no reason why wages should remain as high as they are. While I am not in favor of reducing the workingman's wages as a rule (?), yet I think it would be far better for the unemployed to work in the mines for \$2 a day than to be seeking work in the Park or around the city, or any place where they may procure work, at \$1 a day, and most of the time having nothing to do at all."

It is a singular fact that whenever a system of economy is to be inaugurated in any business or industry where a large number of men are employed, the burden invariably falls upon the shoulders of the working classes—the great producers of the commonwealth, who more than any other class "earn their bread by the sweat of their brow." Mr. Chapman is not impervious to the errors of indifferent writers who have taken a similar position previous to the production of his own article. He has fallen into the same snare, and must bear the odium which such ill-advised statements incur.

It is very noticeable that, while the efforts of certain men are always in the direction of the reduction of the wages of the industrial classes, very little is written about economy in other departments where economy could be more properly and rigidly exercised. It is absurd and unjust to ask the working classes to submit to a reduction of wages while the price of labor in other departments remains intact. It clearly shows the bias of a writer's mind. Several reasons may be adduced to show cause why the wages of miners in California should remain unchanged. Every partial and sensible-minded person must admit that \$3 per diem is not too great a compensation for the noble and courageous men who risk their lives while exploring the subterranean depths in search of the precious metals. But few people have a conception of the hardships and dangers to which this class of toilers are exposed while engaged in the pursuit of their avocation; and I surmise that Mr. Chapman is among the class who are ignorant of the existing dangers—dangers to which no other industrial class is subjected—the exposure to caving ground, falling timbers, breaking of cables, explosion of powder, conflagrations, the inhalation of gaseous matter and other noxious effluvia, which have a tendency to bring the miner to a premature grave. This is only a partial list of the dangers to which miners are exposed, but decidedly enough to appeal to the sympathy and common sense of all fair-minded people. For this reason alone are they not deserving of \$3 per diem? But this is not the only reason why the standard of wages should be maintained in our mines.

Mining is a science like all other industrial professions. A man to be a competent miner should be a skillful miner. Brains, skill and energy are as essential to the accomplishments of a successful miner as they are to those of any other profession. Mining is a science that is never fully comprehended, as there is always something new to be understood and mastered. The idea prevalent that any person is capable of working in a mine is very erroneous and misleading; and Mr. Chapman's proposition to bring the unemployed of San Francisco to work in the mines would be productive of queer results. What percentage of the unemployed in the metropolis are miners? How many of them understand the rudiments of mining? It is safe to assert that not three per cent of the whole unemployed of this State understand the rudiments of mining. To bring this army of men into competition with our miners would be putting skilled labor against unskilled labor—a proceeding which would be degrading to the whole mining profession. A thousand such men in a mine could not accomplish as much in a day as one hundred skilled miners to run a drift, to sink a shaft, to stope the ground after it is opened, to put a pump in position and keep it in repairs, to timber a mine to keep the ground from falling—all these

things, however simple and unimportant they may seem to the novice, require skill and experience such as the horde of unemployed do not possess.

And this brings us to the consideration of another important phase of the question, namely, that the best paid labor is always the cheapest. To the uninitiated this may seem ridiculous, but it is a fact which all students of political economy must concede, and which all professors of that science have demonstrated, that skilled labor, however highly paid, is the cheapest labor. This axiom applies as strongly to the employment of miners as to the members of any other profession. Where is the printer who would put a workman on the "case" who was entirely ignorant of the art of typesetting; the machinist who would ask a novice to construct an intricate piece of machinery; the carpenter who would put an unskilled laborer to execute a difficult piece of work; an architect who would ask a miner to draw the plans of a modern residence; a tailor who would ask a farmer to make a suit of clothes? Echo answers where. If all these skilled professions refrain from employing unskilled labor, even though that labor can be procured at so much less per diem, why should the miners be subjected to the competition of a horde of unskilled men such as Mr. Chapman would introduce into their midst? If this gentleman will inconvenience himself to visit this burg, we will guarantee to enlighten him on a subject of which he appears to be ignorant.

SAMUEL BUTLER.

Trinidad Asphalt.

Col. F. V. Greene recently read a paper before the American Institute of Mining Engineers that gives some interesting facts about this product. He says:

The asphalt of Trinidad is found in a so-called lake situated about 100 feet above the sea and about three miles from the shore of the island, at the village of La Brea (the Spanish word for pitch). Its area is about 114 acres; its depth, so far as ascertained by certain rude borings, is reported to be about 18 feet at the sides and 78 feet in the center; and underlying it there is said to be a bed of blue clay. If these figures are correct, the lake contains about 6,000,000 tons of asphalt. Whether these borings are even approximately accurate is, however, very doubtful. It is even contended by some that the lake is still fed from underground sources. The only positive information on the subject is the fact that the excavations of the last ten years (about 180,000 tons) have not appreciably lowered its level.

The word "lake," applied to this deposit, is an entire misnomer. It is a level tract of brownish material having an earthy appearance. Cracks or fissures having a width and depth of a few feet appear here and there over the surface. Some of them are filled with rain water, while others have been filled with soil blown there by the wind and giving support to a scrubby vegetation. Some travelers have reported that the deposit is liquid in the middle, but such is not the fact. Carts and mules can be driven everywhere on its surface. The material is dug with a pick and shovel, loaded into carts, and hauled to the beach. Here it is placed in baskets, which are carried by coolies wading through the surf to lighters, and from these lighters it is loaded on vessels. During the voyage the material unites in a solid mass, and has to be removed again by the use of pick and shovel. On being unloaded, it is placed for about five days in large tanks heated by a slow fire. The moisture is expelled, the roots of trees and other vegetable matters are skimmed off the surface, the earthy matter with which it is combined settles by gravity, and the refined product is run off into barrels. The refining is in reality a mere heating to a liquid condition, in order to allow the sediment to deposit; and great care is taken not to heat the material to a point which will in any way change its chemical condition or produce distillation.

W. M. WILSON, a well-known mining man, has just closed a deal with capitalists in this city for gold properties in Arizona, the purchase price being \$100,000. The property is situated almost on the apex of the Hassayampa mountains, near Castle creek, about half way between Phoenix and Prescott. The ore is low grade, running about \$10 to a ton. It is what is known as Iron specular ore. Mr. Wilson states that there is enough ore on the surface to keep 50 stamps running. Extensive development work will be begun immediately.

IT IS PROBABLE that practical smelting will be added to the curriculum of the School of Mines at the Nevada State University. Professor Jackson, who has charge of that department, has had a quartz mill built and it is now in practical operation. The mill was built by the students under Professor Jackson's supervision, and the Board of Regents will very likely add a smelter so that the students can be practically educated in the art of reducing and smelting ores by every process now in practical use.

A New Centrifugal Chlorinator.

Mr. J. W. Sutton, of Brisbane, was engaged some weeks ago at the Mount Morgan gold mine in carrying out a series of trials on the various kinds of ore there with his small chlorinating, leaching and precipitating plant, capable of treating about two tons per day, the results being exceedingly satisfactory and promising in the near future to make a radical change in the present methods of gold recovery by the chlorination process. The process and apparatus are thus described by the inventor in *The Australian and Mining Standard*:

The chlorinator consists of a wrought-iron barrel lined with lead, containing a central tube perforated and covered with asbestos cloth; attached at the left-hand side of the barrel is a smaller one, also lined with thick lead and has a steam jacket. The whole is mounted on cast-iron trestles and driven with gearing at the rate of four to six revolutions per minute. The ore to be treated is slightly damped and let into the barrel by the doors on the top, from a hopper on the upper floor, and when quite full the hinged doors are screwed up; at the same time a sufficient quantity of salt, manganese and sulphuric acid to chlorinate the contents of the large barrel is put into the smaller one, and the whole set revolving. The chlorine which is at once given off from the mixture passes through an aperture into the central tube of the large barrel and percolates through the asbestos cloth into the ore, the revolving action always keeping the ore sufficiently loose for the gas to enter thoroughly among the ore, and at the same time keeps the chlorine mixture in the smaller one well agitated. When the evolution of gas begins to lag, steam is turned on until all the mixture is decomposed. Valves are placed on the side of the barrel to let out the common air while the gas is entering, thus insuring good and strong nascent gas.

Three hours is found to be sufficient time to convert the gold into chloride; the barrel is then stopped and the contents let into a bopper ready for leaching, at the same time the residue from the small barrel being run out. The leaching machine is a centrifugal similar to that used in drying sugar. It is driven direct by a small engine on top of the framing. The spindle which carries the basket has a coarse pitch thread its whole length, upon which works a drum, which, when down in the basket, leaves an annular space between it and the sides of the basket, which are perforated and lined with asbestos cloth. The ore from the bopper being let down on to the top of the drum, the centrifugal force slides it off into the annular space, and as soon as this is filled a friction cone on the drum top is brought into action, and it is withdrawn clear of a workman's head. A clear-faced body of ore is then revolving at about 300 revolutions per minute, water is turned on this face, and by the centrifugal force is sent direct through into the outer casing, carrying with it all the gold in solution. By this means of leaching only about one-tenth as much water is used as by the ordinary method of vat work, and the time required is only about seven minutes per charge of 10 cwt. When, by the usual test, the solution flowing from the outer casing gives no gold reaction, a small mechanical plow is introduced which scoops the spent ore out of the bottom into trucks or into shoots to be conducted to the waste tailing heap. The solution of gold is then run into the precipitator, which is a rectangular tank with a spindle driven through it from corner to corner and driven by pulley at about 40 revolutions per minute.

Into this precipitator is put sufficient sulphate of iron and kerosene oil, and when half full it is set revolving for about ten minutes, by which time the whole of the gold has been precipitated, and the precipitate thoroughly greased by agitation with the oil, so that when it comes to rest the water with the base metals in solution lies at the bottom, the gold and oil on the surface. A tap is opened and all the water runs away through a safety sand filter, and the oil and gold is then run into a receiver, and thence into a small centrifugal, whereby the oil is immediately separated, leaving the gold in the basket, from which it is simply scooped out and melted, and the oil is taken back for use over again. The plant is capable of treating 30 tons in 24 hours.

A BIG VOLUME of gas has been struck at 80 feet in the E. Archer well, says the *Salinas Journal*. The gas blew pebbles and sand as it came up with a roar through the 2-inch pipe. A match was touched to it, and it is burning to a height of about 12 or 15 feet. The volume of gas issuing from the well is estimated by experts to be sufficient for illuminating purposes for a town of 20,000 inhabitants. The only question is, will it last? Mr. Archer intends to "let her blow" for a while and if the supply continues strong he will make preparations to utilize it. Great crowds visited the locality to view the column of flame as it shot up into the air.

Auriferous Veins of Meadow Lake, California.*

By Waldemar Lindgren.

General Type.—Fissure veins containing auriferous sulphides and arsenides with gangue of tourmaline, quartz and epidote in granitic and diabasic rocks.

By far the larger part of the veins of the gold belt of California have a gangue of quartz alone or quartz with some dolomite or calcite, contain free gold besides sulphides, and occur in the sedimentary auriferous slate series or in the eruptive bodies, unaltered or dynamo-metamorphosed, which are connected with them; the large granitic areas are usually barren. The group of veins to be described here shows thus a type which in many respects differs from the ordinary. Indeed, auriferous deposits of this class do not appear to have been mentioned as occurring in any other part of the United States.

Location and Discovery.—The Meadow Lake mining district is situated in Nevada county, about ten miles north of Cisco, a station on the Central Pacific Railroad, at elevations ranging from 7,000 to 7,500 feet. The first divide of the Sierra Nevada, whose summits here reach 9,000 feet, is only eight miles distant toward the east. The climate is severe and snow sometimes falls to a depth of twenty feet on the level. A rough trail leads into the district from Cisco; a wagon road thirty-five miles long leads to Truckee by a circuitous route.

The mines were discovered in 1863 by H. H. Hartley, and a great rush took place to the district in 1865 and 1866. The free gold found at the surface soon gave way to relatively poor sulphides and the boom speedily collapsed. At various times subsequently some work had been done on the principal mines, and only recently the deposits have been subject of some discussion in the technical papers. Considering the difficulties of access and climate, there is some doubt as to whether any of the deposits can ever be worked with profit. The ores will not average more than from seven to ten dollars per ton at the most. Probably \$200,000 or \$300,000 have been expended in the district, while it is doubtful if more than \$75,000 have been taken out.

General Geology.—The area is of a rough, mountainous character, the elevations ranging from 5,800 to 7,800 feet. The vegetation is scant, the soil having been swept away by the Pleistocene ice sheet once covering the region, leaving enormous bare expanses of the prevailing granite rock.

Granodiorite.—A light gray granitic rock occupies the larger part of the area, and in it is contained nearly all of the veins. The rock is in general identical with the gray so-called granite that occupies such large areas in the Sierra Nevada and which probably extend through southern California far down into the peninsula of Baja California.

The rock consists of typical development of feldspar, quartz, biotite and hornblende with medium grained hypidiomorphic structure. The soda-lime feldspars are usually considerable and to a variable extent in excess of the alkali feldspars. The silica varies between 60 and 73 per cent; the amount of lime is variable, but it rarely exceeds while it usually falls somewhat short of the sum of the alkalis. While in some varieties which cannot be distinguished from the others in the field, there is more potash than soda, a frequently occurring relation is 2 per cent K_2O to 4 per cent Na_2O . It will be seen that the rock very closely approaches some quartz-mica-diorites and often might be indicated by that name.

This term, however, besides being clumsy, does not sufficiently express its close relationship to granite, brought out by its frequently high percentage of silica and low percentage of lime, by its variable percentage of alkali feldspars and by the muscovite sometimes occurring in it. On the survey maps of the gold belt of the Sierra Nevada, of which district Mr. G. F. Becker is geologist in charge, it has therefore been determined to indicate this rock as *granodiorite*, which term it is hoped will find general acceptance.

Age of Granodiorite.—The granodiorite is later than the quartzite slates of Signal Peak or Red Mountain north of

Cisco, which have been extensively metamorphosed by it. As these sedimentary rocks are the direct continuation of the series which a few miles farther south at Sailor canyon have been identified as Jura-Trias from the meager fauna occurring in them, the granodiorite evidently postdates that period.

At Meadow lake several interesting facies of the granodiorite occur. Near the diabase contact it appears darker and more basic by increasing hornblende. West of Meadow lake from the Keystone mine up toward French lake there is no biotite, but at many places a monoclinic pyroxene appears and the rock contains abundant titanite. At several places near French lake a peculiar augite-diorite occurs composed of quartz, plagioclase and augite; the areas of this rock, connected by transitions with normal types, are distinguished by the brilliant white color of the glaciated outcrops.

Diabase.—An area of diabasic rock occupies the eastern margin of the map, adjoined on the west by dark basic diorite. It is sometimes, as at Meadow lake dam, rather a ruralized diabase-porphyrity; at Fordyce dam, farther south, it is a biotite-diorite. The relations of the diabase to the granodiorite are not clear beyond doubt, but the latter appears to be the younger rock.

Andesite.—Several small masses of andesitic breccia of late Tertiary age cover the older rocks to the west of Meadow lake; north and east of it large masses of this volcanic rock appear.

Ore Deposits.—The granodiorite area contains between Signal Peak and Meadow lake a great number of black veins and seams composed of quartz, tourmaline and epidote, together with grains and smaller masses of pyrite. In certain places the latter mineral, and other sulphides have been formed to a large extent and are auriferous enough to render their exploitation possible. The strike is northerly or northwesterly, the dip vertical or at high angles to the northeast; the width of the veins is variable; sometimes, as at Excelsior, it reaches 12 feet. The walls are frequently indistinct. The veins near Meadow lake do not seem to be traceable for long distances, while some of those of Old Man mountain, which is a rounded granitic dome, traversed in several directions by fissure systems, appear to be continuous for half a mile or more. The country rock is not extensively altered in the vicinity of the veins. Many small veins occur at the contact of granodiorite and diabase near Meadow lake and a few are also found in the latter rock just south of the lake.

Ores.—The ores consist of iron pyrite, arsenical pyrite, pyrrhotite, zinblende, and rarely galena; on the decomposed surface much coarse free gold occurred which, however, was soon replaced by the sulphides mentioned and in which the gold occurs in extremely fine distribution.

Auriferous copper ores prevail at the Keystone, with cuprite, chrysocolla and other secondary minerals. At the most developed mine, Excelsior, iron pyrite is the most abundant ore. Silver does not occur to any notable extent in the ores.

Gangue.—While some white quartz with admixed sulphides occur, the usual gangue is a black, hard and dense rock of sometimes almost basaltic appearance, in which the ores are disseminated. In more coarse-grained specimens yellow epidote, quartz grains and small radiating aggregates of a dark brown tourmaline are visible. Under the microscope the black veinstone is resolved into an interlocking aggregate of quartz grains, occasionally traversed by cracks along which comminution and crushing has taken place; gas and fluid inclusions are plentiful; epidote and sometimes zoisite form aggregates in places; tourmaline occurs as irregular grains with the quartz, but much more commonly as slender crystals and radial aggregates intimately and plentifully imbedded in the quartz. The tourmaline has pleochroic colors varying from bright brown to dark bluish or greenish gray. Skeleton crystals are common, the interior being filled with quartz grains and bunches of radial chlorite. This latter mineral is quite common in some slides, sometimes traversing the tourmaline in small veins. Brown mica occurs in aggregates, together with tourmaline. A colorless mica, titanite, ilmenite and some calcite were also observed. The ores occur intimately intergrown with this gangue. In one case pyrite was observed surrounded by a ring of pyrrhotite.

In a small vein occurring where the trail to Meadow lake crosses Fordyce creek grains of a faintly greenish monoclinic pyroxene, and probably also a little albite, occur together with abundant quartz, tourmaline, epidote and pyrite. The occurrence of pyroxene in veins of this class is certainly not usual. Pyroxene is, however, not exclusively an igneous mineral; Daubree has long ago shown that it may be formed by the action of superheated water on glass containing iron, and, according to Brogger, it sometimes occurs in the veins of the syenite of southern Norway, together with zeolites and calcite in such a way

that it must be regarded as having been formed contemporaneously or even later than the zeolites.

From the data given above it appears probable that the larger part of contents of the veins should be regarded as country rock intensely altered by solutions containing heavy metals and boron, ascending along narrow cracks and fissures.

Somewhat similar deposits have recently been described by W. Moericke from Chili. In these occurrences a hornblende-biotite-granite of probably Tertiary age is in the vicinity of the veins altered to a tourmaline rock nearly identical with that here described; the veins proper occur in this tourmaline rock and consist of quartz with but little tourmaline, together with auriferous copper ores.

New Gold Extraction Process.

The extraction of gold in a simple and economical manner by an electrolytic process, capable of dealing with every kind of refractory ore, is stated to be the lately accomplished result of the long study and experiment on the part of a London chemist, says the *Philadelphia Record*. There are several electro-chemical processes already in use for obtaining gold from refractory ores, in which such deleterious substances as sulphur, iron oxide, arsenic, zinc, etc., are associated with the gold. But it is found that no one particular process is available for every class of ore. Hence much money is often expended on an extensive plant for treating a certain kind of ore, which has to be abandoned or supplemented by another plant, when the character of the ore changes. The main requirements in these processes are: First, the circulation of the pulverized ore between positive and negative poles; second, a solvent liquid for the gold; third, means of collecting the electrolyzed gold; and fourth, the concentration of the positive pole.

In the new universal process the first requirement is met by having a screw propeller set vertically near the bottom of the tank. The solvent is a dilute solution of potassium cyanide, and the collection of the gold is effected by a bath of mercury, which constitutes the negative pole. The positive pole consists of a mixture of powdered pitch or rosin, consolidated by heat.

In operation, the ore, mixed with a certain portion of water, is placed in the tank, with the bath of mercury at the bottom. On starting the screw the mixture circulates down the center of the tank and impinges gently upon the surface of the mercury. It then travels up the sides of the tank, which are conical and on which the positive pole is laid, and back, down to the center, to be again driven into intimate contact with the mercury. The gold is thus brought into contact with an active instead of a sluggish mercury surface, over and over again, until every particle of gold has been seized and absorbed.

It is stated that some of the most refractory and typically difficult ores have been submitted to this process, and that in some cases over 90 per cent of the contained gold was extracted.

The chief advantages claimed for the process are that the gold is extracted directly from the ore without any other preliminary treatment than crushing; that the same chemicals are used over and over again; that the process efficiently extracts the gold and silver from the auriferous ores, whether refractory or free; that the precious metals are obtained at once from the amalgam in the metallic state, without further chemical treatment, and that any workable quantity of ore may be treated in one vessel at one operation, and the gold obtained in one day.

Spelter, Copper and Lead.

The production of spelter in the United States in 1893 was about 74,500 tons of 2000 pounds, as against 83,619 tons in 1892.

The production of copper from domestic ores exceeded somewhat the output of 1892, notwithstanding a heavy reduction in the output of the Anaconda mine, which mine curtailed production when the market was low. On the other hand, the Calumet & Hecla considerably increased.

The production of lead in the United States declined only in domestic desilverized, which amounted to about 122,000 tons of 2000 pounds, and of antimonial lead 5300 tons produced. The sort lead of Missouri and Kansas was almost the same as in 1892 and amounted to 31,300 tons, while the lead produced from foreign ores amounted to about 23,000 tons, and foreign bullion refined here in bond to less than 35,000 tons. The entire production was, therefore, 159,600 tons from foreign ore and bullion.

DURING the month of January the Enreka and Palisade Railroad Company received in transit to Salt Lake and Vallejo Junction, Cal., 1226 tons of ore from Eureka district and other mines, as follows: From the Diamond, 747 tons; Eureka Con., 181 tons; Jackson, 105 tons; Richmond, 87 tons; Phenix, 46 tons; Idaho, 41 tons, and Hamburg, 20 tons. There were no shipments from White Pine, the ore teams having all been laid off for the winter.

*Meadow Lake district (formerly Excelsior) was at one time the center of a vast amount of interest in California. Soon after its discovery there was a great exodus to the camp; and in a very short time mills were erected, mining operations were in active operation, and a city had sprung up on the shores of the lake. But the unprofitable character of the ore was soon apparent, and the population of the district vanished as rapidly as it gathered. Buildings—some of them brick—were left with their furniture, mills with their stamps complete. It is the most pitiful instance of the sudden rise and equally sudden death of a mining camp in the history of California, though there are parallels in Nevada. For the past twenty-five years there have been various attempts to revive interest in the district, and the "process man" has often attempted to work the ore. The belief, long cherished, in its high value has been gradually subsiding, until lately the truth is known. The accompanying paper is a valuable contribution to technical literature on the subject, and will be especially interesting to the many who know the history of the district, and, perhaps, shared in it. It may be interesting to know that H. H. Hartley, discoverer of the Meadow Lake veins, died about a year ago after thirty years' residence in the district, during which time his faith in its value never wavered. His widow is said to be now in San Francisco endeavoring to carry out his life work—to secure capital for the development of the Meadow Lake mines. The paper is from the *American Journal of Science*.—EDITOR PRESS.

Hydraulic Mining.

A REVIEW OF THE INDUSTRY BY DR. HENRY DEGROOT.

In Eight Parts—Part VIII.

The Undercurrent.—This is a large, shallow kind of sluice from 20 to 50 feet wide and 40 to 50 feet long, with sides 16 inches high, set on a heavy grade at the side of and a little below the main sluice, the design of it being to relieve the latter of the finer material and permit of its handling the remainder more effectually. This structure is located at a point where there is grade to spare for a drop in the main sluice, across which there is here set an iron

inch plank, tongued and grooved, is set on an eight to ten per cent grade. It is paved with cobbles or small blocks. The gravel escaping from the undercurrent is caught in a side sluice and returned to the main line.

Formerly a sort of subsidiary undercurrent set beside and below the principal structure was in use, but they have latterly come to be discarded.

A view of the latest style of undercurrent with its details is shown in the accompanying cut.

Miscellaneous Items.—In size, hydraulic claims are apt to cover a large area. Longitudinally, they extend from half a mile to four or five miles, running with the course or

method of measurement being adopted where the banks are shallow and therefore of large area. A cubic yard of gravel in place varies in weight from one and one-half to one and three-fourths tons, the weight when broken down being somewhat less.

The causes of the disparity appearing in the tabulated exhibit requires some explanation. That the product of gold per cubic yard and the cost of labor, water, explosives, should have been so much less during the earlier part of the period over which operations extended was due to the fact that during these earlier years the material washed consisted of the top gravel, which, being loose, required fewer explosives for breaking it up, as well as less water for running it off; it being at the same time poorer in gold than the gravel lower down. The latter being heavy and cemented, required not only more powder to loosen it up, but also more water to carry it into and through the sluices, which, it will be observed, were kept on the same grade all the while. As a matter of course, the banks on either hand grew higher as washing was carried to greater depths.

The wages paid by the hydraulic companies in California range from \$2 to \$4 per day, the latter to superintendents and foremen. In the drift mines a larger number of men are engaged, but here many of them are Chinamen, whereas the hydraulic companies employ only white labor.

The money invested in the hydraulic mining properties in California approximates \$100,000,000. Some of the larger companies have expended each fully \$3,000,000, this including purchase of property, cost of prospecting and equipping with plant. These mines were, at the time they were enjoined, making an annual output of between six and seven million dollars. Had they been permitted to continue operations, this output would by this time have amounted to ten million or more annually. This business, at the time it was arrested by legal proceedings, had been brought to a high degree of efficiency, its methods and mechanisms, through long and costly experiment, having been thoroughly perfected. As a consequence it had become not only the least hazardous, but the most profitable style of mining extant.

grating. Through this grating the finer material drops into a box paved with blocks and set at right angles to the main line of sluice; the coarser stuff which passes over the grating being picked up by sluices set on a lower level, the box meantime discharging its contents through a chute into the undercurrent. This chute, which is paved with cobbles

supposed course of the Pliocene or other channel on which they are located. As these channels are sometimes very tortuous, these claims require to be of considerable width in order to cover all their bends and angles. The titles of all the large and many of the smaller companies consist of United States patents. The right to carry their ditches

put would by this time have amounted to ten million or more annually. This business, at the time it was arrested by legal proceedings, had been brought to a high degree of efficiency, its methods and mechanisms, through long and costly experiment, having been thoroughly perfected. As a consequence it had become not only the least hazardous, but the most profitable style of mining extant.

over the public land is secured to the miners by law.

The value of the gravel piped off in hydraulic washing is measured by either by the cubic yard, by the number of inches of water used or by the yield per acre, the latt

A New Gold-Extractor.

Mr. Saupe, of Melbourne, has shown us a plan of a new quartz crushing machine invented by him, says the *Mining Standard*, which is designed to operate without the use of water. The material is fed into the pan of the crusher, and when pulverized is drawn out by means of an exhaust pan, and is thrown into a screen in the separator or extractor. This screen, revolving, is covered with wire gauze of four different gauges, and delivers the crushed material into four hoppers, from whence it is blown on to their respective tables, depositing the matter into hoppers in degrees of fineness regulated by gravity. The gold is then separated from the hater matter and deposited in its box. Mr. Saupe has been highly complimented on his invention by many practical men.

The Water Supplies in the Arid Regions.

Part I.

By J. W. Powell, Director of the U. S. Geological Survey.

In the western half of the United States agriculture is in part dependent upon irrigation, or the artificial supply of water. The extent to which such agriculture can be carried on depends, first, upon the amount of water which a growing crop requires, and, second, upon the amount of water which can be artificially supplied. In considering these questions it is necessary to use some unit for the measurement of water, and for this purpose one that is simple and practical is readily found. Land is usually cultivated by acres, and water can be measured in terms of acres. An acre of water one inch deep may be known as an *acre-inch*, and an acre of water one foot deep may be known as an *acre-foot*. The first problem to be solved is this: How many acre-inches of water are necessary for the adequate supply of an acre of growing crop for one year? There are two methods by which this can be determined, and it is found that substantially the same conclusion is reached by either method.

I. THE AMOUNT OF WATER REQUIRED.

1. For more than a century scientific men have been engaged in determining the amount of water which various plants will consume through their roots and exhale through their leaves, the process being known as transpiration. This investigation has been pursued by various methods and by different men, and a common general result has been obtained. It has been found that different kinds of plants require varying amounts of water. Deciduous trees require more than coniferous trees with needle-shaped leaves. In general, grasses, vegetables, cereals and fruits require a relatively large amount of water, as will be seen by the following statements:

Grass growing in turf will transpire in one day a weight of water a little greater than the weight of the dried grass.

Many vegetables will exhale in one day an amount of water as great or greater in weight than the dried plants.

Cereals, such as wheat, oats, barley and corn, will exhale their dry weight in water every day.

Perennial vines and trees that bear fruit, such as the grape and the apple, will exhale every day a weight of water equaling the weight of the dry growth of the year.

Assembling these facts, the following general statement can be made: All average cultivated plants will daily exhale an amount of water equal to the dry growth of the plant for the year. This growth is effected in varying times with different plants. Some plants continue their growth for 75 days, others for 150, or even longer; but in general the plant requires for good growth water amounting to about 100 times the weight of its yearly growth when dried. Thus, a ton of hay requires 100 tons of water for its growth. The hay is not perfectly dry, but the loss by complete drying about equals the weight of the dry stubble and roots. An acre-inch of water weighs 226,600 pounds, or about $11\frac{1}{2}$ short tons. Two tons of hay require 200 tons of water, which is about 18 acre-inches. If the crop of hay on an acre is two tons the grass will transpire 18 acre-inches of water.

The Duty of Water.—We thus turn proportions into measured quantities by acres of crop and acre-inches of water, and we have a statement of the acre-inches of water which it is necessary to supply to an acre of growing crops for one year, which may be called the "duty of water." This duty of water, then, as here defined, is the amount of water in acre-inches which will be required by an acre of growing crop for one year. In stating this duty of water it will be given for an average growth, not for the maximum growth, as will afterward be explained.

When There Is Variation.—There are variables to be considered in this problem; that is, the duty of water will depend upon latitude, altitude, humidity of the air with clearness of sky and kind of crop. In northern latitudes plants need less water than in southern; in higher altitudes plants need less water than in lower; in more humid conditions of the air plants exhale less water than in arid conditions, though there seem to be some curious exceptions to this; and, finally, some plants require more water than others. But these variations are not so great but that they may be safely neglected for the general statements herein proposed, and it may be stated that an acre of average growing crop will require a mean supply of water of 18 acre-inches. This will be called the absolute duty of water.

Absolute and Possible Duty.—When water is applied to the land by pipes and all possible precautions against evaporation are taken—the ground well prepared and the water applied in such a manner that there is no loss by overflow, no loss by seepage, and a minimum loss by evaporation either by reason of mulching or shallow surface cultivation—at least two acre-inches of water will be lost by evaporation from the soil. We have, then, the absolute

duty of water as 18 acre-inches and the possible duty of water as 20 acre-inches.

The Practical Duty.—For average crops, all water given to the land in excess of this amount evaporates from the surface of the land or runs away over the surface and underground, and is therefore wasted. But all such waste of water cannot be avoided except at an impracticable cost. In putting the water on the land some amount must necessarily be evaporated. Under good conditions of cultivation, therefore, it is believed that six acre-inches of water must be added to the 18 inches; so that, in the western half of the United States, the mean absolute duty of water, plus the practically unavoidable evaporation, is 24 acre-inches for every average acre of crop. Otherwise stated, an acre of growing crop will drink up by its roots and exhale by its leaves an acre of water 18 inches deep during one season, and in applying this water under economic conditions an acre of water six inches deep must be wasted by evaporation. The absolute duty of water is 18 inches; the possible duty, 20 inches; the practical duty, 24 inches.

EXPERIENCE SUSTAINS SCIENTIFIC INDUCTION.

2. When the last census was taken it was found that an area of about four million acres of land was cultivated by irrigation in the western half of the United States. These lands were scattered widely over the whole region in small tracts; so that the experience of irrigators in this country is already extensive and highly diversified in relation to latitude, altitude, atmospheric humidity and crop. In taking the census many other facts were collected, and among these were the amounts of water actually supplied to the lands by the farmers themselves. It was generally found that the farmers are putting more water on the land than is really necessary, and that this extra amount is usually recognized by irrigators as excessive. The excess occurs in part through evaporation and in part by overflow onto other lands not irrigated, and still another part is lost underground by seepage. The general average in practice was found to be about 30 inches. It was further found, however, that in a few places, where for economic considerations great care was demanded, the duty of water was actually brought down to nearly 20 inches. Thus the widely diversified experience of the farmer is a reasonably approximate confirmation of scientific induction. But this 20 acre-inches is sufficient only when the water is carried in watertight canals or in pipes, and the ground is thoroughly prepared for its reception, and the most advantageous methods of applying the water are used. Excluding the very exceptional cases, good practical irrigation requires 24 acre-inches of water. Any amount additional to 24 inches put upon the land is not only wasteful of water, but injurious to the crop, as will hereafter be shown.

The conclusion is thus reached that the mean absolute duty of water for the arid region of the United States is 18 inches, the mean possible duty 20 inches, and the mean practical duty 24 inches; and all water put upon the land in excess of 24 inches is an injurious duty.

Important Qualifications.—With regard to the duty of water, as heretofore set forth, some very interesting and important qualifications should be made. The quantity of water which has been given as necessary for growing crops is for average crops, not for maximum crops. It has been found by numerous experiments that the growth of most crops can be greatly increased by providing conditions for the utilization of a greater amount of water. If the soil is underdrained and properly prepared, and the water supplied with the proper fertilizers, a much larger production can be realized than that which our farming usually secures. The water supplied to the plant is the vehicle of the materials wrought into the plant. Those who have studied this subject with great care state that the crop can be doubled, or even multiplied five-fold, by properly supplying it with water and plant food. But, under these circumstances, water supply must be increased proportionately. Suppose the farmer could control all the conditions, as the gardener can in his hothouse covered with glass, then 150 or more bushels of wheat, barley or corn could be raised on an acre of land. But 60 to 100 inches or more of water would be necessary. Again, it is found that in order to secure the maximum growth of plants, certain careful conditions of supply must be observed. Some plants will grow in water; a few cultivated plants will grow in marshes.

It is found by experiment that the growth of the plant will be checked by checking the water supply, which must be continuous to the most successful; that if checked the plant adapts itself to the new conditions, and, if afterward the normal supply is given, the plant will not avail itself of the better condition. It is also found that if the plant is urged to its greatest capacity by the best conditions during the early part of its growth, and until the grain or fruit has nearly attained its full size, and the water supply is then diminished, the yield will usually be increased and improved in quality; if the leaf growth is then checked, the fruitage is increased.

Sonora Mines.

Mexico enjoys a well-merited reputation for the extent and richness of its numerous mining properties that extend throughout a vast portion of its territory. The State of Sonora, Arizona's nearest neighbor to the south, possesses its full share of notable properties, both gold and silver production, and among them the Colorado mine, not far from Torres station, is a constant contributor to the gold output of that section of the country, says the Arizona Enterprise.

This mine is situated nearly due south of Tucson, and is reached by a run of twenty-four hours from Benson over the Arizona & New Mexico Railroad. The train stops at Torres, the station from which the mine is reached, for breakfast. This point is ninety miles from Guaymas, and has an elevation of 700 feet above sea level. The mine lies thirteen miles east of the station, 600 feet higher, and is reached over one of the best roads in the country. The well-known Minas Prietas is but a quarter of a mile distant from the Colorado, but its old-time activity has departed.

The Colorado has reached a depth of 550 feet, with extensive drifts at its several levels. At 500 feet the ore body is from 14 to 24 feet wide, and this level is now being worked. The 400 level has nearly 1,000 feet of development, and the 300 level has about 1,600 feet. The mine is well opened from the first to the fifth level, exposing a very large body of ore. Superintendent Howell Hinds says there is sufficient ore in sight to supply the thirty-stamp mill and twelve Frue vanners and the Huntington mill for ten years. This mill treats ten tons every twenty-four hours, and the concentrates average \$175 per ton. The thirty-stamp mill treats eighty tons per day, and from fifteen to twenty tons are shipped.

About 350 men are employed in various capacities about the camp. Common laborers receive from \$1.25 to \$1.50 per day in Mexican coin, and are paid daily if they so desire. Some of the natives are paid \$2 to \$2.50. American mill men receive \$4 to \$7 in gold, and this class includes shift bosses, foremen, mill men and engineers. Wm. McCormick is foreman of the mill; James Goodman is chief engineer; Z. Taylor and Geo. Shelly are engineers at the mine. Pedro Pinelli is acting as foreman of the mine during Jerry Holland's illness.

Thirty thousand galloons of water are taken out of the mine every day. This, added to that pumped from a canyon three miles distant, gives the company plenty of water. The tanks are of stone and built at a higher elevation than the mine and have a capacity of 160,000 gallons. Electricity is used for lighting purposes, and lights are placed in the various offices and residences.

The hoist has been enclosed with a high board fence to further prevent people from stealing the rich ore.

Superintendent Hinds must be highly commended for his satisfactory management of the property that has always met the cordial approbation of the Mexican authorities. While others complain of their treatment, this company has had no cause for regret at having made its investments in Mexico, and Mr. Hinds says that if foreigners will act honestly with the Mexican people they will meet with honest treatment in return.

The Criston mine is about 4,000 feet southeast of the Colorado mine. A pipe line is being laid and the engine is in place. A double-compartment shaft has been sunk 160 feet, and a Huntington mill will begin work on the ore of this promising claim. Many tons of arrastra tailings can be seen surrounding this property, where Indians mined many years ago. Superintendent Howell Hinds and Pedro Negro own the property.

At the Minas Prietas water is being pumped from the 600-foot level for the Grand Central mine. This mine is on the same lode as the Colorado, which is the only formation carrying water in that vicinity. The tailings of the Minas Prietas have been worked by the cyanide process very successfully during the past year. It will require at least two years yet to complete the work.

The Las Amarillos has been worked sufficiently to demonstrate its great value. Chicago parties are negotiating for an interest in it. Pedro Negro says over 700 feet of work has been done, and from a number of assays made the lowest was \$20, and from that up to \$233 per ton. This is a very promising claim and is partly owned by Pedro Negro and Jerry Holland.

The Grand Central mine lies west of the Colorado, with but one intervening claim. The shaft is now down 400 feet with a 40-foot ledge to work on, which is said to average \$20 per ton. The shaft will be sunk 100 feet deeper. This mine was worked on a lease by the Minas Prietas company, and up to the expiration of their lease they had taken out over \$1,000,000. For the past year a ten-stamp mill has worked twenty-eight tons daily. Superintendent Seymour and family reside at the mine. E. A. Brown and J. R. Emerich are at the mill.

Scientific Progress.

The Canals of Mars.

The straightness of the so-called canals on the planet Mars makes an explanation of their presence difficult, says an exchange. There is no parallel on this earth. They are too straight to be cracks in the surface, rivers or mountain ranges. Carl Winslow says that the cause must be looked for in other heavenly bodies, as it is probably too powerful to be found in the planet itself. A planet, an asteroid, striking Mars would make a straight line on the surface where it scored it, and the theory that the peculiar straight marks observed on the planet are caused by collisions is supported by the fact that Mars is more exposed to such collisions than any other planet. Between Mars and Jupiter are innumerable asteroids. Their orbits are very eccentric, and some of them are at times nearer the sun than to Mars. As their orbits traverse that of Mars, the possibilities of collisions are the greater. If the collision is tangential the meteorite will make grooves or furrows like those now known as canals. This will happen when the velocity is greater than that of Mars. If very great, the meteor will continue its course. Another theory is that the canals which have caused such widespread comment are but optical illusions.

The Heat from the Sun.

Those who have paid attention to this subject are aware that the remarkable doctrine first propounded by Helmholtz removed all real doubt from the matter. It is to this eminent philosopher we owe an explanation of what at first seemed to be a paradox. He explained how, notwithstanding that the sun radiates its heat so profusely, no indications of the inevitable decline of heat can be as yet discovered, says the *Fortnightly Review*.

If the sun had been made of solid coal from center to surface, and if that coal had been burned for the purpose of sustaining the radiation, it can be demonstrated that a few thousand years of solar expenditure at the present rate would suffice to exhaust all the heat which the combustion of that great sphere of fuel could generate. We know, however, that the sun has been radiating heat, not alone for thousands of years, but for millions of years. The existence of fossil plants and animals would alone suffice to demonstrate this fact.

We have thus to account for the extremely remarkable circumstance that our great

luminary has radiated forth already 1000 times as much heat as could be generated by the combustion of a sphere of coal as big as the sun is at present, and yet, notwithstanding this expenditure in the past, physicists declare that for millions of years to come the sun may continue to dispense light and heat to its attendant worlds with the same abundant prodigality. To have shown how the apparent paradox could be removed is one of the most notable achievements of the great German philosopher.

What Helmholtz did was to refer to the obvious fact that the expenditure of heat by radiation must necessarily lead to shrinkage of the solar volume. This shrinkage has the effect of abstracting from a store of potential energy in the sun and transforming what it takes into the active form of heat. The transformation advances pari-passu with the radiation, so that the loss of heat arising from the radiation is restored by the newly produced heat derived from the latent reservoir.

Such is an outline of the now famous doctrine universally accepted among the physicists. It fulfills the conditions of the problem, and when treated by arithmetical calculation it is not found wanting.

The Formenophone.

The formenophone, quite recently invented by Mr. M. E. Hardy, is an apparatus designed to trace in air the presence of any gas having a different density. His fundamental idea is as follows: It is a well known acoustic principle that if two organ pipes of the same pitch are sounded simultaneously by means of blowers, fed by pure air, we hear a simple sound; but if we force through one of these pipes pure air, while the other is thrown into vibrations by means of a mixture of air and gas, the sound of the latter pipe is correspondingly modified; consequently when the two pipes are sounded simultaneously, a certain number of interference heats will be heard, depending upon the quantity of gas contained in the air with which the pipe is fed.

The formenophone, the apparatus by means of which this experiment may be made, consists of two blowers and two pipes exactly alike. One of the blowers and its appropriate pipe is enclosed in an air-tight box containing pure air. The other pipe is fed by a mixture of air and gas. Each experiment takes but a short time, lasting perhaps a few seconds.

The formenophone is directly applicable to the detection of the quantity of coal gas in coal mines, and may be so constructed as to

give continuous indications not only in the mine, but also in the chief engineer's office.

If used for this purpose, a microphone with a receiving telephone is placed upon each organ pipe. When the two pipes are in unison, the sound is clearly reproduced by the telephone, likewise any interference heats that may occur.

To avoid the trouble of holding the telephone constantly to the ear, M. Hardy substitutes for it an amplifying microphone consisting of an electro-magnet mounted upon the poles of a permanent magnet. A vibrating steel spring carries upon its free extremity a conical piece of carbon. Another light, insulated spring carries a flat disk of carbon which lies upon a conical piece of carbon. The current of a local battery traverses the two carbons, and then passes through a large receiving telephone fastened to the wall of the room. Thus the receiving telephone repeats the sound of the microphone amplifying the latter about 400 times, and any heats are easily heard throughout a large room.

Professor Tyndall's Daring.

The late Professor Tyndall thought no labor too great and no risk too excessive to be undertaken on behalf of his beloved mistress, Science. One experiment he conducted specially illustrated this. Knowing a layer of iodine placed before the eye intercepted the light, he determined to place his own eye in the focus of strong invisible rays. He knew that if in doing so the dark rays were absorbed in a high degree by the humors of the eye, the albumen of the humors might coagulate; and, on the other hand, if there was no high absorption, the rays might strike upon the retina with a force sufficient to destroy it. When he first brought his eye, undefended, near the dark focus, the heat on the parts surrounding the pupil was too intense to be endured. He, therefore, made an aperture in the plate of metal, and, placing his eye behind the aperture, he gradually approached the point of convergence of the invisible rays. First the pupil and next the retina were placed in the focus without any sensible damage. Immediately afterwards a sheet of platinum foil placed in the position which the retina had occupied became red hot.

Liquid Fuel in Germany.

Liquid fuel, in the form of petroleum refuse, has been tried with such success by the German naval authorities on a small scale that Signor Cuniberti of the Italian navy, has been invited to visit Germany and conduct further experiments.

Steel in Car Construction.

At the December meeting of the Western Railway Club, Mr. J. D. McIlwain, of the Harvey Steel Car Works, gave an interesting description of the cars exhibited at the World's Fair in whose construction steel was employed to a greater or less degree, and also of the extent to which that metal is used in other countries. He stated that it has been demonstrated that a steel-frame car can be built that will embody 150 per cent, or $2\frac{1}{2}$ times greater resisting strength, at least 300 per cent longer life, cost 50 per cent less for maintenance, and weigh 15 to 20 per cent less than the modern American wooden car. As to its being necessary to have special machinery to repair steel cars, he stated that every well-appointed railway locomotive and car shop is equipped with punches, shears, cold saws, bulldozers, etc., and that is about all that is needed to frame and form material for renewals and repairs of steel parts. If standard sections are used, very little forging will be necessary.

If put together on car-building lines, and not like a boiler, it will be as easy to remove and repair bent or defective parts as in a wooden car. The evolution would be gradual from wood to steel. The same would be the case with appliances for repairing. The cost for any change in the repairing plant would be small compared to the reduced amount of repairs required with the use of metal frames. In European and other foreign countries the evolution from wooden to metal cars has been quite rapid. It having been demonstrated that the metal car costs much less for maintenance than the wooden car, yet the difference in cost of metal and wooden cars is much more than it is or will be in this country, as they build a car there without much regard to future cost of maintenance, which is a very important item in this country. Thus far our metal cars have been built with a view to future maintenance, which is a consideration absolutely necessary.

The question of dead weight is of considerable importance. To obtain a steel car with 15 per cent less weight than a wooden car of the same capacity means a saving in cost for haulage of 15 per cent, which insures a less number of cars to do the same amount of business, a less number of cars to maintain and renew, making a very marked reduction in the cost of rolling stock.

Fire-Resisting Glass.

Glass having unusual fire-resisting properties has recently been produced in Germany, and competitive tests have been held to ascertain the merits of samples from several factories. The glass was put into the vertical windows and skylights of an old building which was then set on fire, and sudden changes of temperature, shocks from weights and jets of water and other means were employed to prove its toughness. Excellent results were attained, especially by the glass from the Siemen works in Dresden, which withstood a temperature of 2140 degrees Fahrenheit for half an hour.

Speed of Trains.

The real danger in increasing the speed of expresses driven by steam does not lie in incidental risks. It is not denied that modern locomotive might be built which could run up to 90 or possibly 100 miles an hour, if the lines were straight. It is the curves of the existing lines which render any such speeds impossible, unless the weight of the engines and trains were also increased far beyond what the bridges and permanent way would bear. At the first sharp curve the 100-mile express would fly off the rails. The necessary relation of these curves to speed is accurately known, and it is that, and not the lack of power,

or novel dangers from wind pressure or boiler explosions, which sets the limit to modern train speed. As the force tending to throw off the line a train running at the speed of 150 miles an hour would be about six and a half times greater than that which a steam express train resists at a curve when running at 62 miles an hour, it is plain that the present lines could not be used for the "lightning express," even though the electro-motor were substituted for the steam engine. The lines must not only be stronger, but straighter than would be possible by any modification of their present forms.—Kuhlows.

Nature's Models.

When a man competes with Nature in engineering problems he is left far in the rear, says the *Engineer*. This is particularly the case in the appliance of power for speed. The wild duck is about the last bird we should expect speed from; it has enormous surface, is very heavy forward, and has a comparatively long neck and a heavy head, with all it has very small wings, but a wild duck is one of the swiftest birds in flight, surpassed only by the wild goose, which is even more heavily handicapped. The whale is a lumberly craft—so to call it—modeled on the lines of a Dutch galliot. Its propellers are exactly the reverse of what we should suppose the correct position, lying horizontally on the water when at rest, instead of being vertical in it, as a vessel's propellers are. Moreover, the flukes of the whale's screw are very small indeed, and are also the reverse of what man makes. They have the least surface at the tip and are largest at the hub—or junction of the body—but a whale goes through the water with this apparatus like a fast steamboat, and can tow a heavy whaleboat full of men at a most surprising velocity for a long time. These instances prove our contention—that we have a good deal to learn yet in the application of power to bodies moving through fluids, either of air or water.

Interesting Gun Experiments.

The Armstrong Gun Company recently showed some very interesting experiments with the latest ordnance. A 6-inch gun was fired four times in 20 seconds, an 8 inch gun three times in 30 seconds. A torpedo was driven satisfactorily with powder. There was a search light which would keep its beam upon an object no matter how violently the vessel rolled. A 10-inch 30-ton gun, when it was fired, opened the breech screw by the recoil and wound up a spring, when released, would close the breech again. A 4-7-10 field howitzer anchored itself after the first discharge by driving a spade-shaped plate into the ground, after which its recoil was met by a jacket which surrounds it. A 6-inch gun, with light portable disappearing mountings, for a siege train, could be taken apart so that no portion weighed more than three tons, ten hours being required to mount it. A 6-inch naval gun fired five rounds in 69 seconds, each time at a different range and target. A plate of special steel designed for a shield received rifle and Gatling-gun fire at 100 yards range without a single penetration, while the plate hitherto used penetrated at every shot, the Gatling gun almost cutting it in two.

New Firebox.

A steel firebox, chiefly for locomotives, to supersede the present expensive copper boxes, has been designed by Herr Bacillek, an Austrian engineer. The corrugated steel plates, raised to a cherry-red heat, are quenched in a bath of a certain composition which has the effect of rendering the metal more capable of resisting the heat of the fire, while the corrugation of the plates not only diminishes the number of stays required, but also increases the amount of heating surface.

Useful Information.

Austria's New Gun.

The military authorities are still extremely reticent concerning the mechanism of the new Austro-Salvator mitrailleuse, or quick-firing machine gun, but a correspondent learns that the firing trials made at the Vienna arsenal have been reported upon as highly satisfactory. The weapon has been adopted by the service, and fully 100 pieces are now ready for distribution. The gun, according to the *London Standard*, is not intended for use in the field, as in the case of the English Maxim and Nordenfeldt machine guns. The new mitrailleuse will be mounted stationary on the outworks encircling important fortresses.

It is only half the weight of the Maxim, and its average rate of discharge is about the same—300 rounds per minute, with a maximum of 320. The diameter of the bore is eight millimeters, being similar to that of the Mannlicher repeating rifle now in use in the Austrian service. The barrel is not incased in a water jacket, and 1200 continuous rounds can be fired before it shows the effects of the excessive heat. The cartridges are supplied, as in the Nordenfeldt, from a large "hopper" fixed above the firing chamber. The gun is fired by means of an ordinary trigger with trigger-grip, and a recoil spring supplies the automatic action.

But the principal point of interest in respect of which the new gun differs entirely from the mechanism of similar weapons now in use in other countries is the oscillating pendulum regulating the speed of fire. There are two firing commands with the Maxim—"single fire" and "continuous fire." The discharge is regulated by the turning of the crank handle. The single fire is as the fire from an ordinary repeating rifle, while the continuous represents the most rapid discharge of which the machine is capable. With the Salvator mitrailleuse, however, the great advantage is gained of sustaining a moderately heavy discharge of 30, 50 to 100 rounds per minute, and increasing it by means of a faster oscillation of the pendulum to 300 when a dangerous phase of the attack has been developed. The saving of ammunition thereby is enormous. The mechanism is said to be very simple, and throughout the trial no jams were recorded. The Austrian military authorities naturally congratulate themselves on the excellence of this new invention.

Making Postage Stamps.

Every part of postage-stamp making is done by hand. The designs are engraved on steel, 200 stamps on a single plate. These plates are inked by two men, and then are printed by a girl and a man on a large hand press. They are dried as fast as printed, and then gummed with a starch paste made from potatoes. This paste is dried by placing the sheets in a steam fanning machine, and then the stamps are subjected to a pressure of 2000 tons in a hydraulic press. Next the sheets are cut so that each one contains 100 stamps, after which the paper between the stamps is perforated, and after being pressed the sheets are filed away. If a single stamp is injured the whole sheet is burned.

Another Ship Canal.

The revival of interest in ship canals has already awakened a deep interest in New Jersey for the building of such a canal across the State, says the *World's Progress*. The canal could be dug through clay and marl from Bordentown to the Raritan, near New Brunswick, a distance of $33\frac{1}{4}$ miles. It would pass for 12 miles along the bed of the Raritan canal, then following the beds of the Stony brook and Laurel brook. It is estimated that it would cost \$25,000,000, and

that it would accommodate ocean steamers of 27 feet draught. This canal would benefit a section of country containing 20,000,000 inhabitants. By its use the voyage around the State of New Jersey to and from New York, a distance of over 180 miles, and all the dangers of ocean storms would be obviated. The trip through the canal, including all lockage, could be made in six hours.

Monkeys Make Pottery and Wine.

An extraordinary story is told by the *London Daily News*, which states that Dr. Macgowan has returned to Tien-tsin, bringing with him, among other curious discoveries, some particulars of a race of Manchurian monkeys inhabiting the mountain region of the great wall of China. They are said to know how to make pottery—more remarkable still, they are represented as having made extraordinary progress in the art of making wine. A recent edition of the official history of Yungking states that lately a large body of immigrating monkeys passed a certain village in crossing from one mountain to another. The boys of the village clapped their hands and shouted at the spectacle, and the monkeys, being frightened, fled, taking their young in their arms, but dropping in their flight a number of earthen vessels, some of which would hold a quart. On opening these the villagers found that they contained two kinds of wine—a pink and a green—that had been made from mountain berries. It is affirmed that the monkeys store this liquor for use in the winter when the water is all frozen. Dr. Macgowan cites other independent testimonials to similar facts, including a Chinese account of monkeys in Chekiang, who pound fruit in stone mortars to make into wine, and he asks: "Is it likely that all these statements are pure inventions?"

Wonderful Canal System of France.

An official document shows that the length of navigable waterways in France is some 8000 miles, of which 650 are returned as tidal, 2100 miles navigable without works, 2250 miles canalized rivers, and 3000 miles of canals, and of this vast network of interior navigation, the government has all but seven per cent in charge, the system having been brought to its present condition at a cost of \$300,000,000 for construction and purchase, and \$25,000,000 for concessions, with an annual cost, also, of \$325 per mile, average, for maintenance. The number of vessels employed on the waterways is about 16,000, and of these 26 per cent have a capacity of 300 tons or more, while more than half of them have a capacity exceeding 100 tons; the number of foreign boats also using the French canals yearly is said to exceed 2000. The motive power is now almost entirely furnished by draught animals, though a few steam tugs are used on the Seine, the Oise and some other rivers, and steam cargo boats are occasionally met. Cable towing and tow locomotives are resorted to a limited extent.

The Electrical Horsewhip.

It seems doubtful, says an exchange, whether objection can be brought against the latest form of horsewhip, which is constructed so as to give a slight electric shock to the animal. The handle, which is made of celluloid, contains a small induction coil and battery, the circuit being closed by means of a spring push. The extremity of the whip consists of two small copper plates insulated from each other, each of which is provided with a tiny point. The plates are connected with the induction coil by means of a couple of fine insulated wires. As a means of surprising a sluggish animal into doing his best work without the infliction of physical pain, the electrical horsewhip will, by many, be hailed with gladness.

BOOKS ON ASSAYING.

By C. H. AARON.
Part I.—Gold and Silver Ores.
SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning.
The work, like Mr. Aaron's former publications "Testing and Working Silver Ores," "Leaching Gold and Silver Ores," that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:
Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assay; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.
The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1893. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.
Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.
SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion; Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.
Table of Contents:
Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Oxy Sulfate Method; Volhard's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.
One of the methods given for the Assay of Copper is new original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.
Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market St., San Francisco.

Electricity.

Electricity in 1900.

The editors of four of the leading authorities, in response to an invitation to give their ideas on the probable development of electricity and its application, promise some wonderful changes before the dawn of the next century. The editor of the *Electrical World* says: "We can expect no great improvement in dynamos and motors, as they now return in electricity as high as 97 per cent of the energy supplied to them. The arc lamp is practically perfect electrically, and, while notable improvements may be made in the present form of the incandescent lamp, nothing startling can be expected. Electric railway traction will undoubtedly supersede all other methods for urban use, and by the extension of networks in the country, promises to largely revolutionize rural life; its application, however, to long trunk lines seems improbable. The electrical transmission of power will receive enormous extensions and probably entirely take the place of steam power within a radius of several hundred miles of water powers and in the vicinity of coal fields, whence the energy of coal will be distributed by means of the electric current instead of the coal itself being transported. The electric light will probably entirely supersede all other kinds of illumination in cities, towns and thickly settled rural districts, and electric motors will gradually enter into all operations requiring power, and more and more narrow the field of the steam engine, if, with the gas engine as an ally, it does not drive it out entirely. Telephoning across the Atlantic is a probability, and seeing by electricity a possibility."

The editor of the *Electrical Review* also believes in the sure advent of the transatlantic telephone, the further development of the transmission of electric power, and especially an elaboration of the domestic use of electricity. On this last point he says: "Electric heating is now an important element in the rapidly extending railway business, replacing the disagreeable and dangerous coal stove, and is advancing into the domain of the coal furnace and gas range, bringing cleanliness, convenience and economy with it. When fully perfected and understood, the electric heater will be one of the greatest boons that the electrical engineer has given us. Every housewife will rise up and call him blessed, and every husband will bless him and not rise up! He can file abed and increase or originate heat in room and kitchen by simply turning a switch or pressing a button. Even this effort may be dispensed with, and a clockwork attachment press the button automatically."

The editor of the *Electrical Age* coincides with this prophetic view of the household run by electricity. This is his view of what we will have by the year 1900: "I expect to see our homes, offices, stores, etc., heated by electricity. This system of heating is entirely practicable, the only question involved being the all-important one, cost. It probably will be made popular by supplying electricity from large central stations through street mains, connecting the premises therewith. Electricity may then be used for cooking and doing what mechanical work may be necessary about the house, store or factory. It can be made to perform all of these duties by simply turning a little handle or pushing a button. Electricity will be used to accomplish a thousand and one different things to save us labor, and in directions little dreamed of at present. New things and applications are being constantly developed; it only needs more popular familiarity with them to find a wider use for them."

The editor of *Electric Power* joins all these and goes even further. Among the items of his prophetic vision are some bits of domestic beatitude like the following

"In 1900 we shall probably have brought down the cost of current and of utensils to such a degree as to allow even people in moderate circumstances to use the cleanly current instead of the coal or gas stove. Then will the millennium of the servant girl have broken into dawn. The overhead or trolley system will very probably be superseded by a system not more obtrusive than the cable on Broadway—a conduit system. The cars running underground will be propelled by electricity."

"In six years we can look for the supersession of the incandescent lamp as it is at present by a new lamp evolved along the lines sketched out by Nikola Tesla, whose brilliant discoveries have recently been fully enumerated by our esteemed confrere, Mr. T. Commerford Martin. The new lamp will probably be without filament, but will glow by the luster of a high-frequency current properly employed. There is even a possibility of the present bulb-shaped lamp disappearing, giving way to a long, continuous tube of glass hidden away behind crevices and casting a soft light upon the ceiling and thence down upon the floor. The disinfection of the city will probably be effected by the agency of electricity. The canal-boats will come down to the wharves propelled by electricity. The streets will perhaps be cleaned by an electrically driven brush, and a mighty exhaust fan in city hall, driven by a motor, may serve to purify it."

Electrical Etching.

A German technical journal is authority for the statement that electrical etching has advantages over the usual methods, in that the solution need not be nearly as strong, and that when seen under the microscope the etched lines and edges produced by intersections are quiet even and clean cut, while in the usual method they are rough, due probably to the gas bubbles formed, and the lines are apt to be rough, the metal being eaten away below them; the disadvantages are that the current used requires to be regulated, and that the solution must not be too strong. A detailed description is given of how the electrical method is used. Among other things, it states that it is better to use a solution of the salt of the metal of which the plate is made in preference to an acid bath. A good covering material is made of equal parts of asphalt and copal varnish.

The Bell Patents.

The Bell telephone patents which became open to the public by reason of expiration of term on the 30th ult. are: The combination with an electro-magnet of a plate of iron or steel or other material capable of inductive action, which can be thrown into vibration by the movement of surrounding air or by the attraction of a magnet. The formation in an electric telephone of a magnet with a coil upon the end or ends of the magnet nearest the plate. In combination with an electric telephone, the employment of a speaking or hearing tube for conveying sounds to or from the telephone. There are many improvements and attachments to what is commonly known as the "Bell telephone" now in use, which are covered by patents which will not become public property for many years.

Glass on Wire Netting.

Wire netting has been so coated with glass as to fill up the openings and make a transparent but not brittle roofing and sidewalls. For the glass an insoluble gelatine film has been substituted, and the material, known as "tectorium," is now extensively employed in constructing hothouses, verandas, factory windows and store roofs in several foreign countries. It is tough and flexible, and, if desirable, may be painted any color.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frus machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers, thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurates and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

AT THE ARGONAUT.—*Dispatch:* Work on the Argonaut mine, south of the Kennedy, is progressing finely. The shaft is now down a depth of 125 feet. They expect to sink down 1200 feet before they commence drifting. The indications thus far give every reason to believe that it will prove to be equally as good as the Kennedy when they reach the proper depth.

THE VETA MADRE.—*Dispatch:* N. A. Brady, one of the promoters of the Veta Mining Company, reports that a considerable portion of the stock set aside for working capital has already been placed, and work will soon be commenced on the property. This property is located on the mother lode, south from the Kennedy and Argonaut mines, being a consolidation of the Schober and Bright properties, and was worked to some extent in early days at which time the rock crushed from \$7 to \$10 per ton. Since then several spasmodic attempts have been made to develop the property, but for want of energy or sufficient capital, have proved ineffectual. Heavy croppings can be traced throughout the entire location, and rich stringers of quartz have been encountered in previous developments.

NEW SHAFT.—*Ledger:* The South Spring Hill Mining Company will commence work in a very short time upon a new shaft which will be sent down 1500 feet. The shaft is to be located a short distance from the old one and where the ledges of the Median and South Spring Hill can be worked with the greatest facility.

MINES OF DAYTOWN.—*Cor. Ledger:* A large amount of capital has been judiciously expended on the group of mines situated partly in the townsite and known as the Drytown Consolidated, comprising the Olive, Bonanza, Crown Point and Yellow Jacket claims. A shaft about 200 feet in depth was sunk on the Olive, and a five-stamp mill erected and some very good rock crushed from near the surface. The funds of the company becoming exhausted and the creditors filing attachments against the property further developments were stopped. A shaft was sunk on the Bonanza claim 540 feet by the Drytown Consolidated Company; one drift was extended northward 120 feet and one crosscut west about 20 feet. For some reason unknown to many of the stockholders, operations suddenly ceased and the mine was allowed to fill with water. Some very good rock was taken from this mine nearer the surface. A 20-stamp mill was erected by the original Bonanza Company.

The Crown Point adjoining, has a shaft 280 ft. which has all caved at the mouth and the machinery removed. Some rock paying as high as \$18 per ton was taken from this claim. A ten-stamp mill was built on the property. Abundance of water in this Yellow Jacket caused this company to abandon their property after extracting some very rich rock about 35 feet from the head of the creek.

This part of the county lies at such an elevation that the main water supply coming from such a height that almost an unlimited power for milling or manufacturing purposes is attainable. Along the ridges which traverse the county from east to west are located the canals of the water companies so that water can be supplied to nearly every acre of ground both in the mineral and agricultural districts, affording sufficient water to run many mines and factories and irrigate thousands of acres of the best lands in the State for the culture of fruit. The character of this part of the county is generally hilly with many small valleys.

Butte.

SHUT DOWN.—*Forbestown New Era:* The Golden Queen mill has shut down pending the opening of a new working level in the mine.

The Gold Bank mill continues to drop its 40 stamps, and the new development work is constantly being carried on. This mine and mill has now over 100 men on its payroll.

The Denver mill is being run to its full capacity day and night and is said to be paying well.

At the Bullion everything is running smoothly, and a night shift was put at work on Monday.

Work at the Beehive (Mt. Hope) mine is being pushed with all possible speed. All the machinery is now on the ground and it is thought that the mill will be completed in about a month.

Leroy Brothers are opening up a quartz ledge near the head of Perkins ravine. The rock carries some free gold and is rich in sulphurets.

Cataveras.

AT THE McFALL.—*Citizen:* The sinking of the McFall mine goes steadily on regardless of bad weather. The rock looks well and without a doubt this will in time be one of the noted mines of this section. The Ford Bros., who have this mine bonded, are energetic men and are sparing nothing to forward the development of this property.

Nevada.

THE MURCHIE.—*Transcript:* Messrs. Bittenbach and Boeckman, two of the directors and leading owners in the Providence mine, who have been here the past few days, visited the old Murchie mine in company with a mining engineer and inspected the property. They represent a company of capitalists who are desirous of buying a gold mine. They will make the owners a cash offer and if it is accepted the new company will proceed to work the prop-

erty. They intend to expend about \$75,000 in putting up machinery and opening the mine. It is believed that with a 100-stamp mill and facilities for handling the ore cheaply, the low-grade rock can be worked profitably. There is one very large ledge in the Murchie mine property from which quartz enough can be taken to keep 100 stamps running for several years, but it will not pay to work it on a small scale.

CEMENTED GRAVEL.—*Transcript:* Sam Peck, Wells Ashman and a man named Peterson, have been prospecting the cemented gravel in the old diggings near Mrs. Storey's residence on Orchard street. Tests made with a hand mortar and pan were very encouraging, but in order to make a practical working test they have had five tons of the gravel hauled to Locklin's mill to be crushed. If the returns are satisfactory they will make arrangements for putting up a mill and working the gravel on a big scale.

THE LUPINE GRAVEL MINE.—*Transcript:* Men have been started to work on day's pay at this mine, which is situated on the Washington ridge, in the vicinity of the Central House and about 10 miles from this city. Some very rich gravel, with occasional nuggets of gold, have been found in the mine at different times, but the main channel has not been struck, although it is believed that they are not far from it. The Lupine is owned by Nevada City and Grass Valley men, among the leading owners being Hon. John Caldwell, F. T. Nilon, Supervisor E. W. Donnelly and George Mainbart.

Mono.

TO START A MILL.—*Bodie Miner:* J. S. Cain is having the Bodie Tunnel mill overhauled and put in shape for working custom ore. It is expected that there will be considerable to do next spring in the way of crushing small lots of ore for different ones.

Placer.

ON FOREST HILL.—*The Auburn Herald* learns that several new mines are being opened on the Forest Hill divide by parties from San Francisco and Eastern States. Among others, the Labaree mine and the Willis mine have recently been sold and are being opened by their purchasers. One of the largest properties, however, which is prosecuting development work is the Eureka Consolidated, a drift mine of great promise, situated above the now famous Mayflower drift mine. The Eureka Company owns nearly seven miles of the channel. It is arranging to use a small Baldwin locomotive or a motor for running its cars in and out of the mine, the same as the celebrated Bald Mountain mine has adopted. The rate the work is going ahead at the Eureka at present it is expected they will reach gravel before the end of the present year.

TO RESUME OPERATIONS.—*Colfax Sentinel:* The Big Oak mine, situated about a mile from Colfax, is soon to resume operations, after being shut down for several years. It is proposed to run the mine by water from the South Yuba Ditch. Owing to the greatly improved facilities that the ditch brings, it is expected that the cost of running the mine will be greatly reduced. Some very rich rock has been taken out of the mine in past years and there is much reason to hope that the same thing may again be expected.

The Hidden Treasure mine at Sunny South paid a bigger dividend last month than any time in its history. The mine has been paying for the past twenty years. About forty-five white men and a hundred Chinamen are employed at the mine.

The company that has bonded the Willis Gould mine at Iowa Hill commenced work on the same this week. Two shifts are at work pushing the tunnel ahead.

The Golden River mine at Red Point is said to have reduced the white miners' wages to \$2.50 per day, and the Chinese miners in proportion.

James Gayetty & Co. will begin operations on their quartz mine at Secrettown in the early spring.

Plumas.

NORTH FORK MINES.—*Cor. National Bulletin:* Messrs. Harper & Long have struck a very rich mine at Cariboo, a few miles below this place. The gravel on the bedrock runs from \$2 to an ounce to the pan. They have just completed a ditch, which will afford them plenty of water for washing the gravel, and when they get things in running order, large returns may be expected.

The company that leased the Sunnyside mine last fall have now got the mine opened in good shape, and last week struck good pay in the main tunnel; and the daily output of gold is now beyond their most sanguine expectations. Some years ago this mine was worked by a company and yielded many thousands of dollars, but it appears the old company lost the pay streak and closed down the mine without prospecting much to find it. The lessees, some old miners here, have always thought it a good property, as there are 160 acres in the claim and scarcely 20 acres yet worked, which from present appearances will pay as well as any of the ground formerly worked and leave a handsome profit to the lucky lessees.

Mr. Hugh Kelly and son have closed down one of their mines for the winter, after a very successful run of about nine months, and are now running a tunnel in another property to tap the Big Flat channel, which is now attracting considerable attention. A claim on that channel is considered a sure paying mine when once opened, as all those who have tapped the channel have found this to be the case. The channel is large and the rime perfect. Of course, the development of the channel has been slow, owing to the fact that it requires tunnels from 300 to 1000 feet to tap the gravel. This work has all been done by poor men.

From actual figures from those who mined the half mile that has been worked, it has produced \$170,000 in gold, the greater part coming from Glazier mine, on the north end, and the Sunnyside on the south.

Mr. Fred Scott has a force of men steadily employed in his mine and is daily adding to the gold products of Plumas. This mine is also on the Big Flat channel. Although it has been open less than a year, it has paid for all the dead work done and left the owner a handsome profit, with virgin ground enough to last for years to come.

Mr. Angus Cameron, who is also the lucky owner of three claims on the same channel, will soon begin to take out gold. He struck the channel some time ago, in an upraise from the tunnel, and has now about completed another raise some distance from the first, which will give him a circulation of air and enable him to work out a large space of ground. Mr. Cameron washed a few carloads of gravel where he struck it, and his returns were \$2 to the carload of 1500 pounds, which, owing to the locality and convenience of working, makes it a good paying property, and one that will last for many years.

Messrs. Bismick and Mullen are doing some work on the Glazier mine, but as they are working down stream they cannot accomplish much. This claim consists of 130 acres, and out of 20 acres that have been washed over \$60,000 in gold has been taken out, but owing to the fact that they have worked the mine down stream below their tunnel as far as the water will permit, the mine is now idle.

Dick White and son have closed down their mine for the winter. They did very well during the last few months. If they had not erred in placing the wing dam on the pay streak they would undoubtedly have taken out a large amount of gold during the last summer. On running a cut under the wing dam the other day, Mr. White got a pan of gravel that yielded \$12, showing how unfortunate he was in placing his wing dam; but he says he will be able to mine it satisfactorily the coming summer, and profit by his experience.

Rachford & Co. are steadily working their claim and taking out considerable gold, with very flattering prospects.

John Leinhardt and Fred Mori have a force of men employed and are taking out considerable gold.

Stephen Dean has found a very good paying claim, and is taking out some money.

Messrs. Mandeville and Rickard are developing their quartz claims, with very encouraging results. They have cut the vein in the "Cub" mine 150 feet deep. The vein is 20 feet wide, and all prospects, and it shows a chute of ore on this mine to be 1000 feet long and 150 feet deep so far; and as the ore will mill between five and six dollars a ton, with all the natural facilities for working which they have, it makes it a valuable property. They are making considerable money with a machine they have invented to save fine gold in working the surface dirt that has broken away from the vein. In a run of 18 hours with it they cleaned up \$10.90, one man handling the dirt, which is very satisfactory to the owners.

This is a good field for miners prospecting for quartz. Very little prospecting in that line has been done, and all the gold found here shows more or less quartz attached to it, thus showing conclusively that it never came far and only needs some good prospectors to prove this a good quartz country.

ELIZABETHTOWN CHANNEL.—*National Bulletin:* Since our last issue, work at the Elizabethtown Channel Shaft has been resumed. The new engine, after being refitted, was placed in position and steam gotten up yesterday morning. The machinery is reported to work perfectly. Sinking is now in progress and, barring accidents, will proceed without interruption until bedrock is reached.

THE '93 MINE.—*National Bulletin:* Geo. McLearn reports much interest taken in the vicinity of Mohawk looking to the development of the mining industry. In the "93 mine," in which he, Mr. Knickrem and others are interested, very good ore has been developed. It is probable that a company will be organized to work the property on a larger scale. Samples of ore sent to San Francisco give a very high assay. An exhibit of the ore will be found at the Midwinter Fair.

Siskiyou.

GOOD WINTER FOR MINING.—*Yreka Journal:* The miners at Hawkinsville are all busily engaged at present in ground-elucidating, and expect to take out a great amount of gold dust this winter, the season being one of the most favorable yet afforded in the way of free water, and plenty of it. The top dirt sluiced off by the flood of water and granite pays very good wages, and the bedrock cleaning next summer is expected to yield immensely.

John Napper, who has a good placer and quartz claim just this side of Joe Piper's blacksmith shop on Humburg, is making preparations for extensive operations in the spring, as there will be an abundance of water to continue work all summer with good success, in consequence of the great amount of snow on the highest peaks of the Humburg range of mountains. Other miners all along the creek are also making similar preparations, and we may anticipate one of the best mining seasons ever experienced on that famous gold-producing stream of both quartz and placer claims.

Martin Schuler, who is engaged in drifting at Scott river, has taken out several fine specimens of coarse gold lately, and expects to take out considerable gold this summer.

Tuolumne.

THE BUCHANAN.—*Independent:* This fine old mine is still being vigorously prospected under the superintendency of Chas. Holland. Stopping from the old adit level is now in progress.

A crushing of 250 tons has just been completed, the result being entirely satisfactory. The sulphurets have a value of \$60 per ton, with a percentage of about 24, and are easily chlorinated and treated. This property is well equipped with a 20-stamp mill, with eight Frue concentrators, and a chlorination and assay office complete.

NEVADA.

Washoe District.

LAST WEEK ON THE COMSTOCK.—*Consolidated California and Virginia mine*—1650 level.—In continuing our prospecting work from the drift run north from the foot of the upraise on the sill floor of this level, we have extracted a few tons of ore of ordinary value. The drift running from east crosscut 1 from the drift north from the winze down 52 feet has been extended six feet; total length, 22 feet; face in porphyry and some quartz. From this north drift at a point 200 feet in from its mouth an east crosscut has been advanced 18 feet, so far in porphyry. Very near this point in working upward we have extracted a few tons of ore assaying \$28 per ton. Total quantity of ore extracted from all parts of the mine during the past week was 56 carloads—about 55 tons; average assay value, \$30.38 per ton. Most of this ore came from our workings in the vicinity of the winze, 20 feet down. The southwest drift, the Rule drift, from the 1000 station of the Consolidated Virginia shaft has been extended during the week 84 feet; total length, 644 feet. At this terminal point an opening has been cut out on the southeast side of the drift and will be continued up to meet the Best & Belcher drift, which is now advanced to within 46 feet of the connecting point, and which, according to the survey, is 40 feet above the sill floor of the Rule drift. Good progress is being made in the work which remains to be done to effect the connection of the two drifts.

Mexican—1465 level.—The crosscut running west from the drift run south from the top of the upraise which was carried up 45 feet above the sill floor of this level at a point 40 feet from the main north drift and 100 feet north from the south line of the mine has been extended during the week 23 feet; total length, 230 feet; face in porphyry carrying clay separations.

Ophir—1465 level.—The drift running north from the crosscut running west from the main drift on the sill floor of this level at a point 124 feet south from the winze station has been extended 18 feet; total length, 142 feet; face in porphyry, clay and a little quartz carrying a small assay value. An advance of 108 feet has been made during the week in reopening and repairing the central tunnel, making the total length of the drift reopened from its mouth 614 feet. Have continued jointly with the Mexican Company the work of making repairs to the main shaft.

Hale & Norcross—1300 level.—We continue stopping out ore from the winze below this level, and extracted during the week 26 cars of ore assaying \$31.13 per ton per car sample, and five cars of ore, average assay per car sample \$17.55 per ton.

Andes—420 level.—West crosscut 3 from north drift extended 13 feet; total length, 23 feet; formation, quartz and porphyry.

BRITISH COLUMBIA.

GETTING RICH BY INCHES.—Away up in the Big Bend country of British Columbia some valuable mining properties have been reported, and, although capital has not been extensively used to operate the ground with labor-saving machinery, a number of hardy miners have been making good wages with primitive tools. The Kootenay Star tells of some of these. Along the Columbia river the benches are being worked. Sol Holden has one near Smith creek, with bedrock to work on. There is water to the amount of 1000 miners' inches turned on the bench by means of a swinging flume, forcing the gravel ahead into a riffled flume, which tails into the Columbia. They have moved about 13,000 yards of dirt in four seasons and cleaned up nearly \$10,000. Had a good six-inch nozzle been working on the bench they could have mined in three weeks what it has taken the present owners four years to move.

On the McCulloch creek summit quartz claims have attracted some attention. One find has been pronounced by experts to be "tellurium," a metal combined with gold and silver in the ore, which is very rich but refractory. It lies in pockets through the white quartz, the pockets varying in value, and with the small amount of development work done so far it is impossible to tell whether they are bonanzas or only a dream. Assays from this ore have gone thousands of dollars to the ton.

The Consolation mine, on French creek, was paying over \$35 a day to the man when last heard from, and, with only four men employed, will take out something like \$20,000 this winter.

The owners of the Selkirk mine have reached pay after years of battling with peculiar geological conditions. At the upper end of the claim there has apparently been a great waterfall. Above this fall the country rock is hard and in position. The formation below is shale, which has fallen from the mountains on both sides and covered up the old channel of the creek to an immense depth. Above the fall the gravel is only two or three feet deep on bedrock. The old-timers of '65 and '66 worked this for about a mile, and, it is estimated, took out gold amounting to considerably over \$1,000,000. Old cabins, rusty tools, rotting sluice-boxes, and such articles used in mining, are there to-day, silent emblems of one time life and busy industry. To reach bedrock below the falls the Selkirk people started down stream about half a mile and drove a straight tunnel against the grade of the creek. When last heard from the tunnel was in 700 feet, and at a depth of over 100 feet they had gone through the shale and were in the top gravel.

on the old channel of the creek. Almost anything is possible when bedrock is reached, and it will create no surprise if they come upon the biggest pockets ever heard of in the history of gold mining.

MONTANA.

THE COPPER COMPANIES.—Bntte *Inter-Mountain*: The Anaconda Company is working the Anaconda, St. Lawrence, Green Mountain, Mountain Con, High Ore and Modoc mines. All the other copper companies are working as usual. The Cressus, Snnyside, Buffalo and Adelaide mines, all Anaconda properties, are being worked under lease. Three sets of leasers are working on the Adelaide. J. R. B. Coon & Co. have a lease there and have struck some good copper ore. The Wappello, Amy & Silversmith, Goldsmith No. 2, Missoula, Murray Fraction, West Elba, Blackbird, Soudan and Eveline are all producing silver ore. Bennett & Clark are getting some rich ore from the Goldsmith No. 2. Wm. Forbis' bonanza Eveline mine is producing richer ore than ever, and the prettiest ore ever seen in the district. Bernard's placers in Missoula gulch are being developed for quartz, and some good ore is being shipped from there.

OREGON.

NEW ORE BONIES.—Baker City *Democrat*: The energetic development work that has been pursued by mine-owners in the Virtne and White Swan districts is hearing fruit. Several of the properties show ore bodies wonderfully rich in gold, and within 60 days there will be such a field opened to capitalists seeking investment that great activity will naturally follow. It is not saying too much when the statement is made that before the close of the present year there will be a dozen or more mines equal to the White Swan in operation on an extensive scale.

FOR HYDRAULIC MINING.—Roseburg *Review*: C. O. White of Tacoma has shipped his extensive plant of mining machinery to Myrtle creek. It is proposed to use it in working the great beds of gravel along the Umpqua river, on the Hadley place, about a mile from town. Mr. White claims to have a process by which he can separate the fine gold from the gravel, and he will put a force of about 60 men at work as soon as his machinery is in place.

Good Nuggets.—Rogue River *Courier*: The Messenger boys have been washing a dry gulch high above the waters of Williams creek during the recent freshets and have 10 nice little nuggets, of an aggregate value of \$150, to show for their work of about 10 days duration. If water could be gotten up there, the boys would soon grow rich, as there is an abundance of just such dirt as they washed during the 10 days' wetness.

STROOK A BONANZA.—Rogue River *Courier*: Enos Mallory has struck a six-foot fissure of gold-bearing quartz in his mine at the top of Old Baldy, six miles southeast of town. The ore assays \$250 to the ton and there is every indication that the ledge is permanent, as it has been tapped by tunnels nearly half a mile apart.

CLEAN-UP.—Jacksonville *Times*: A partial clean-up at the Golden Fleece mine produced a 16-pound piece of amalgam. Operations on the mine are being conducted day and night. Two promising ledges of cinnabar have been unearthed there lately.

Two carloads of machinery, consisting of a quartz mill, concentrator and equipments, have been ordered from the Filston Iron Works of San Francisco for the Mountain Lion mine, and are expected to arrive in a few days.

The S. P. Co. has made a reduction on the freight rate of ore shipped from Ashland to San Francisco. Ore worth under \$50 per ton pays \$5 per ton; under \$100, \$6.60; over \$100 and not exceeding \$300, \$8.60. The ore must be shipped to the Selby smelting works, of which Chas. S. Allmen, assayer for the Ashland Mining Co., through whose efforts the reduction was made, is the agent.

LOANS AND MINES

Loans negotiated on first-class securities. Mines and mining prospects of guaranteed value sold on working bonds. **C. H. DWINELLE, Grand Hotel, San Francisco, Cal.**

J. F. OROSETT,

628 Sacramento St., San Francisco, Cal. Gold Mines Bought and Sold on Commission. Five first class meritorious mines now for sale at from \$25,000 to \$800,000. Correspondence solicited.

PRACTICAL TREATISE ON HYDRAULIC MINING.

By AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdy, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For Sale by DEWEY PUBLISHING CO., 220 Market St., San Francisco, Cal.

Double-Acting Cornish Plunger.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER. AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, besides doing away with heavy balance bobs often carrying from 25 to 50 tons of balance. Works with 25 per cent less power. First outlay about one-third less. Suitable to any underly or downright shaft. Friction reduced to a minimum. Occupies less space in the shaft. Has been tested about a year and proved to work satisfactory in every respect.

GUARANTEED TO GIVE SATISFACTION.

Special attention is called to this new feature in the drainage of mines and raising water generally, by which a continuous discharge of water is produced on the up stroke and down stroke, instead of on the down stroke only, which is effected by very much less than one-half the weight of machinery now in use.

When the ordinary pump becomes too small for the work it can be replaced by the new one, using the same rod and column, and doubling the discharge of water, a most important advantage in small shafts where there is not room for a larger pump.

THE CALIFORNIA DEBRIS COMMISSION having received petitions to mine by the hydraulic process from Daniel W. Albert in the Union mine, near Brownsville, Yuba Co., to deposit tailings behind dam in dry ravine; from Tausteno Camp in the Campo mine, near Brownsville, Yuba Co., to deposit tailings in old hydraulic pit; from J. M. Wetmore in the Herring Ravine mine, near Brownsville, Yuba Co., to deposit tailings behind a dam in a ravine; from W. W. & W. A. Lemmon in the Conduit Ravine mine, near Brownsville, Yuba Co., to deposit tailings behind a dam in the Letson ravine; from James Gordon in the Motor mine, near Brownsville, Yuba Co., to deposit tailings in old hydraulic pit; from Crane Bros. in their mine at Sharon Valley, near Brownsville, Yuba Co., to deposit tailings in old hydraulic pit; from the Spring Gulch Mining Co. in the Spring Gulch mine, near San Andreas, Calaveras Co., to deposit tailings behind dam in Obili gulch; from Joseph Snow et al. in Snow Bros' mine, near Newtown, El Dorado Co., to deposit tailings behind a dam in Webster creek; and from H. B. Havens in the Green Meadow mine, near Glenn, Calaveras Co., to deposit tailings behind dam in dry ravine, gives notice that a meeting will be held at Room No. 92, Flood Building, San Francisco, Cal., March 6th, 1894, at 1:30 P. M.

Assessment Notices.

GOULD & CURRY SILVER MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Virginia, Storey County, Nevada.

Notice is hereby given that at a meeting of the Board of Trustees, held on the 31st day of January, 1894, an assessment (No. 73) of Fifty (50) Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 3rd day of March, 1894, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on THURSDAY, the 23rd day of March, 1894, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Trustees.

ALFRED K. DUKBROW, Secretary. Office—Room 69, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

 " 6-foot " Plain Belt Frue Vanner..... 800, f. o. b.

SAN JACINTO ESTATE, LIMITED,
 Office of General Manager,
 P. O. Address, South Riverside, San Bernardino Co., Cal.
 CAJALCO, Dec. 13, 1891.

MESSRS. ADAMS & CARTER, 132 Market Street, San Francisco, Cal.—GENTLEMEN: After a continuous trial of different concentrators comprising the Frue Vanner, the "Holland," "Paradox," "Triumph" and the "Woodbury" concentrators, extending over several months, we find that we prefer the Frue Vanner, as it is easier of adjustment, runs smoother, has less wear and tear, and—having a positive travel—gives less trouble than the other more complicated and ever changing machines now in use here. The Frue Vanner not only saves a cleaner concentrate, but has less loss in the tailings, and is in several ways preferable to the other concentrators here.
 I am, my Dear Sirs, Yours faithfully,
 S. HARRIS, Manager.

For any information, or for pamphlets, or for circulars or testimonials, call on or address

H. J. SUMMERHAYES, Successor to Adams & Carter, Agent for the FRUE ORE CONCENTRATOR.

 Secretary and Manager. }

CAN BE SEEN IN OPERATION AT THE PACIFIC BRANCH UNION IRON WORKS, 127 FIRST STREET, SAN FRANCISCO.....OFFICE, 116 DAVIS STREET

NINETY-FOUR AND ONE-HALF PER CENT

—SAVED—

ON ORES DIFFICULT TO CONCENTRATE.

A MARVEL of Simplicity, Durability and Effectiveness, combining both Side and End Motion with a Bumping Belt. SPEED AND INOLINE of belt and amount of PERCUSSION easily and quickly regulated, WHILST IN OPERATION. CAPACITY about ten tons. Only one-tenth horse power required. Adapted for either canvas or rubber belts.

PRICE (at present).....\$350 EACH,
 Including Prepared Canvas Belt.

FALLS MINE, IGO, SHASTA CO., CAL., May 25th, 1893.

THE MCGLEW CONCENTRATOR COMPANY: I take much pleasure in endorsing your very superior Ore Concentrator. When I was requested to examine your concentrator, I did so under protest, declaring that I would have none other than a Frue, as after many years experience with different concentrators, I believed them to be the best.

Now, after a thorough trial of the McGlew Ore Concentrator, on ore difficult of concentration, I emphatically pronounce it the best concentrator of any I have ever used in handling my ores. It is doing CLEANER and CLOSER work than I had believed possible for any concentrator to accomplish.

Samples of pulp and tailings, taken every hour, dried, mixed and assayed, show * * * from West ledge, a saving by your concentrator of 94 1/2 per cent; from East ledge, * * * a saving of 92 per cent.

The concentrator runs very easy and requires but slight attention. One man attends to rock-breaker, crusher and concentrator. You have a good concentrator, and it can be relied upon to handle any ore that will concentrate. I most heartily recommend it to the mining public. Yours respectfully,
 E. L. BALLOU, Propr. Ballou Reduction Works.

MANUFACTURERS FOR THIRTY-THREE YEARS.

CALIFORNIA WIRE WORKS

LOS ANGELES AGENOY, LOS ANGELES, CAL.

MINE BELL SIGNALS

ADOPTED, USED AND IN FORCE IN ACCORDANCE WITH STATE LAW.

FOR THE CONVENIENCE OF OUR READERS IN THE MINING COUNTIES WE PRINT IN LEGAL SIZE, 12x36 INCHES, THE MINE BELL SIGNALS AND RULES provided for in the Voorhies Act, passed by the State Legislature and approved March 8, 1893. The law is entitled "An Act to Establish a Uniform System of Mine Bell Signals to be Used in All Mines Operated in the State of California, for the Protection of Miners." We can furnish these Signals and Rules, printed on cloth, so as to withstand dampness, for 50 cents a copy. MINING AND SCIENTIFIC PRESS, 220 Market St., San Francisco.

Dredge for River Mining

It is a notable fact that California has been unsuccessful in its efforts to secure gold in river beds by dredging. Several methods have been tried, but they have generally failed. It is true that here and there, in places exceptionally favored with very rich gravel, appliances have been devised, with a little success; but these efforts have been crude and not such as to find general or systematic use throughout the State. Several reasons have been ascribed for these failures. One is the presence of howlders and too much rock; another of too much fine sand. These failures are all the more conspicuous because river dredging for gold has been successful elsewhere. In New Zealand and Australia dredging is extensively practiced. One dredge at work in Victoria (Australia) was made in California.

Of late, in the Northwest, a great deal of attention has been devoted to the operation of the Bucyrus steam dredge, made by the Bucyrus Steam Shovel and Dredge Co., South Milwaukee, Wis., which has been in

BUCYRUS STEAM DREDGE IN RIVER MINING.

cylinder 78 inches in diameter, having openings in each end, through which the material is received and discharged. This cylinder is formed by a double screen, with an annular space between them, the inner screen being of heavy steel plate, with coarse holes punched in it, and the outer screen being of fine wire cloth. Of the material dumped into the cylinder, the stones and coarse gravel are retained by the inner screen and ejected by the revolving bucket in the discharge end of the cylinder. The finer gravel is retained by the second screen after passing through the first, and also ejected, while the sand and gold particles sift through both screens into the tank. About one-third of the cylinder, being the part containing the material, is submerged in the tank, and therefore the material is subjected to the most thorough washing and tumbling during its passage through the cylinder. The length of the internal helix is 72 feet, so each particle of gravel is tumbled over that length of coarse screen, during washing. Similarly the finer material is tumbled over 120 feet of screen in the

BUCYRUS STEAM SHOVEL IN RAILWAY WORK.

operation on the Snake and Columbia rivers, it is said, with signal success. The system is elevation of the gravel by a shovel and securing the gold by amalgamation. The dredge (which is shown in the accompanying illustrations)

in its adaptations to river and land work, does not need extended explanation. But the amalgamator does. It consists of a wrought-iron tank, lined with amalgam plates. In one end of the tank is mounted a revolving

outer helix, thus securing more perfect washing and screening than could be accomplished in any other way in a similar space. The construction of the helix and ejecting

ILLUSTRATIONS.—Bucyrus Steam Shovel in Railway Work; Bucyrus Steam Shovel in River Mining, 129.
EDITORIALS.—Dredge for River Mining, 129. The Silver Situation; California Mines at the Midwinter Fair; An Oregon Assayer's Troubles; A Great Geographical Society; Miscellaneous, 130. The Anti-Debris Association Again, 131.
CORRESPONDENCE.—One More Reply to Mr. Chapman; Mountain Mines—Tuolumne County, A Steam Hydraulic Plant, 132.
MISCELLANEOUS.—Limitations of the Gold Stamp Mill, 133. Quartz Belt of Butte County; The Snow Sheds; The Coolgardie Fields; Harvard University, 134. The Water Supplies of the Arid Regions; The Greatest Bullion Output; The Kern County Mines; Roasting Tailings, 135. The Deep Leads of California; Willows Used to Build Dams; Up the Klamath River; The Alaska-Treadwell Mine; Direct Treatment of Pulp by Cyanide, 137. Slickens; The Gold Output of South Africa for Five Years, 131. To Make Non-Flowing Wells Flow, 132.
SCIENTIFIC PROGRESS.—Air Reduced to a Solid by Cold; Inter-Relation of Forces; The Stethophone, 137.
MECHANICAL PROGRESS.—A New Method of Exchanging Messages Between Ships; An Ingenious Smoke Consumer; A New English Torpedo Boat, 138.
USEFUL INFORMATION.—The Name of California; Secret of His Health; Crossing the Limbs While Sitting; Lemon Juice for Gout, 138.
ELECTRICITY.—Heating by Electricity; Light Without Heat, 142.
MINING SUMMARY.—From the Various Counties of California, Nevada and Other Pacific Coast States and Territories, 141.
THE MARKETS.—Eastern and Local Metal Markets; Coal and Coke; Mining Share Market; Sales in San Francisco Stock Board; Notices of Meetings; Assessments; Dividends, etc., 143.

A SAN FRANCISCO PAPER is conducting a popular contest to ascertain which county has the best mineral exhibit at the Midwinter Fair. The trouble with this sort of contest is that it determines nothing, and the county having the finest exhibit may or may not secure the award. The issue depends upon the numbers and energy of the friends of the several counties. If they "rustle," they secure more "coupons" than others. That is all there is to it.

STATE MINERALOGIST CRAWFORD has just stated to the San Francisco Associated Charities that he is unable to give information pertaining to placers in this State that could be worked by the unemployed. In order to make 50 cents or \$1 a day, he said it was necessary for men to understand mining. Much of the placer ground is covered by agricultural patents, and the owners would not permit the surface to be torn up even if the old ditches for conveying water were intact. The bureau had no record of unappropriated or low-grade abandoned shallow placers. This is just about the situation in a nutshell. The agitation for sending the unemployed of the city to the mines has been made by those who misapprehend the conditions. The unemployed would starve to death before they could earn their way, even if they found placer ground from which a few colors might be obtained.

It is interesting to note the epochs in the history of mining and metallurgy in the United States. They are thus placed by Hon. Abram S. Hewitt, in his presidential address, delivered in 1876, before the American Institute of Mining Engineers: First—The building, in 1774, of the first steam engine in America. Second—The rise in gold mining in the Southern States, about 1828. Third—The opening of the anthracite fields, about 1830, and the introduction of anthracite as a blast furnace fuel, in 1839. Fourth—The use of raw bituminous coal in the blast furnace, in 1840. Fifth—The development of copper mining at Lake Superior, in 1845. Sixth—The re-discovery of gold in California, in 1848. Seventh—The commencement of regular production of quicksilver at New Almaden, about 1851. Eighth—The announcement of the Bessemer process, in 1858. Ninth—The development of hydraulic mining, about 1853. Tenth—The rise of Lake Superior iron mining, about 1856. Eleventh—The development of the Comstock lode, in 1859. Twelfth—Advancing in all departments of the iron and steel industry, including the Martin open-hearth process, in 1868. The seventeen years that have elapsed since this historic retrospect have had their red letter days in the calendar of progress, and in future historical delineations will mark the bright points of divergence and advance. It is interesting and suggestive in this geography of progress to note the concurrence of discoveries in promoting the industrial welfare of the nation.

The Silver Situation.

The result of the recent had break in silver prices has been the more complete prostration of the industry, with no immediate prospect of a revival. A number of mines still running in Colorado—the Smuggler, Pontiac, St. Joe, Mineral Farm and others at Aspen, and the Big Amethyst at Creede—have just closed down and canceled all contracts, and it is announced that they will remain closed until the price at least covers the cost of production. The suspension of shipments from these properties will have a disastrous effect upon the smelters, which had made arrangements to put out the fires in one half their roasters and withdraw from the market as unlimited purchasers of gold ore until they can get a supply of fluxing ores. The smelters, since the panic of last July, have lost heavily from the constant depreciation in the value of their stock. The Omaha and Grant smelter is currently reported to have lost \$150,000 from this cause since the time named. Thorough demoralization of the stock market has likewise ensued in Denver; Molly Gibson, for instance, having within a short time gone from \$7 to \$1. Gold stocks have been likewise affected. The Cœur d'Alene mines had already been suspended, and the Leadville are producing ores only for fluxing purposes. The Comstock is doing little. These are given as the leading illustrations of the effects of the broken market. The same conditions prevail pretty generally throughout the silver districts of the United States.

It is a curious thing that, despite the lamentable condition of the silver industry, and of nearly all other branches of business in the United States, Congress is determined to defeat any sort of legislation looking toward the rehabilitation of silver. There is little prospect that the Bland seigniorage bill will pass. It would seem that the country had not suffered severely enough from the results of the recent panic, and has not sufficiently understood the object lesson afforded by paralyzed industry and unemployed and starving labor. Now that silver is down to 60 cents, it will probably have to go down to 50 or 40, and carry wheat and other great staples with it, before the cause of the world's hard times can be appreciated. An effort is being made just now to ascribe the depression to tariff agitation and the Wilson bill. While this is undoubtedly a contributory cause—some of the objections to this measure have been pointed out in these columns—the root of the trouble is the unsettled financial policies of this and other countries. The present industrial depression is world wide; the tariff question is a mere local affair. It is absurd to say that all nations of the world are suffering from hard times because the United States is unable to determine whether its policy shall be a protective tariff or a tariff for revenue only—a distinction, in a broad sense, without a difference, inasmuch as a certain aggregate of revenue must be raised, and it must be raised by levying a tariff. A tariff for revenue is a protective tariff, inasmuch as the methods of levying are precisely the same, and the difference, where it exists, is in degree, not principle. The income tax and the internal revenue are independent questions, of no importance to the world at large.

The talk of international bimetallicism is undoubtedly increasing. Foreign nations very properly ascribe their own industrial troubles to the abasement of silver, and it cannot be doubted that sooner or later genuine effort will be made to restore it to its proper place.

California Mines at the Midwinter Fair.

The California State mining exhibit at the Midwinter Fair is all that was expected; for it is undoubtedly the finest collection of ores, minerals and specimens ever made in the West. The arrangement of the county exhibits is tasteful and convenient, and designed to show their various features to the very best advantage. The location is in the Mechanical Arts building, where nearly 10,000 square feet are occupied on the ground floor. The exhibit yet lacks its finishing touches, and for that reason complete description of its various features, which, with the exhibits of other States and Territories, was intended to be begun in this issue, must be delayed. For instances, the great globe intended to reproduce the exact hulk of the California gold output is yet to be gilded. A fine obelisk, intended to show in similar manner Sierra county's output, is unfinished. Amador county, which is first on the list (alphabetically), is represented only by two pyramids of ore from the Keystone and Kennedy mines. Five carloads of ore, which have been delayed, are daily expected, and then this fine county will be adequately represented. The Trinity county exhibit has been delayed by snows in the mountains, but is expected Monday. Nevada is practically complete, and its aisles are daily thronged with visitors. Butte is rapidly getting into shape, and will have everything in readiness within a very few days. Siskiyou, Shasta and Calaveras

appear to be all ready, but seem to have nobody in charge whose business it shall be to explain their respective merits to visitors. This is a very notable want, and should by all means be supplied.

The exhibit has been opened to visitors for some days. Supt. Benjamin thinks that in about two weeks the last thing will have been done to make it perfect. But, as a matter of fact, it is now ready for visitors, and its deficiencies have been so carefully covered as to scarcely receive notice. That is to say, if all work were suspended to-day (after gilding had been placed on the California globe and Sierra obelisk) a large, attractive and varied exhibit of California's mineral resources would remain. The great marble, sandstone and granite triumphal entrance is in place. The Marshall statue is in position, and the James Lick group of the discovery of gold in California occupies a conspicuous position in the main aisle. The tout ensemble is to-day little short of magnificent. The exhibit deserves to attract, and will attract, a vast amount of attention.

An Oregon Assayer's Troubles.

It is possible that the responsibilities of an assayer to the mining public will be determined in a case just brought in the Oregon courts. W. C. Bruson, an assayer, has been arrested for obtaining money under false pretenses, in that he is alleged to have made false returns of rock given him for determination. The particulars of the charge are interesting enough to give in full.

Bruson was indicted by the Portland grand jury about two weeks ago. The indictment alleges that early in September Bruson was employed by the Big Bonanza Mining Company, a corporation, to assay some quartz. On the 11th of that month, as is alleged, he "feloniously and falsely" represented to the company that certain ore, rock and porphyry formation which had been delivered to him by E. H. Lewis to be assayed, contained a large amount of gold and precious metals, and each ton of rock of similar kind and quality contained 0.42 of an ounce of gold, each ounce being worth \$20.67. The statement of Bruson was accepted as a true and correct report; but the indictment alleges that it was incorrect. The rock and ore examined, and all of a similar quality, contained only a trace of gold, and the assayer's representations were, as alleged, false and fraudulent. By means of these representations, it is claimed, Bruson feloniously obtained from the Big Bonanza Mining Company 2000 shares of its capital stock, each of which was of the value of \$100. The stock was delivered to Bruson when he rendered his report. Bruson has been released on \$1000 cash bail.

It is, of course, impossible to learn now the merits of a case which has not yet come up for trial; but there will probably be some difficulty in making a case against Bruson. The assay as made by him is really quite a modest one, and suggests the inquiry why, when he was lying (if he lied) he did not do a little better. His opportunities were great, and if he had found it to be \$40 rock he might have secured 4000 shares of stock. The outcome of the case will be awaited with interest.

A Great Geographical Congress.

The following self-explanatory notice has been sent out by the Geographical Society of the Pacific to similar associations throughout the world:

SAN FRANCISCO, February 21, 1894.

MR. PRESIDENT:—The Geographical Society of the Pacific has been requested by the management of the California Midwinter International Exposition to designate a day during the exposition, to be known as "Geographical Day," on which a conference of geographers, and of all those interested in geographical science, will be held under the auspices of the society.

It was the general preference of the members to name Geographical Day, March 16th, proximo, this being the thirteenth anniversary of the organization of the society, which was founded in 1881. However, owing to the length of time required for arranging the numerous details of the exposition, it was found impracticable to place the day so early. We have therefore selected May 4th as a suitable date.

We have the honor to invite your learned society to delegate one or more representatives to be present, or to send a paper to be read at the conference on the day named. Delegates will be entitled, and are requested, to make communications, and to take part in the proceedings.

Very respectfully yours,

Committee of Invitation, George Davidson, Pres.; Th. E. Slevin, First Vice-Pres.; John Partridge, Sec.; H. Durhrow, Treas.; T. F. Trenor, Ass't Sec.

Of 329 employes of the Bunker Hill and Sullivan Company at Wardner, only 84 are Americans native born. From a census compiled by the manager of that company it appears that 17 nationalities are represented on the payroll, as follows:

Americans.....	84	Austrians.....	11
Irish.....	76	Norwegians.....	3
Italians.....	27	Frenchmen.....	7
Swedes.....	24	Danes.....	5
Englishmen.....	23	Swiss.....	2
Scotchmen.....	13	Icelanders.....	1
Welshmen.....	14	Spaniards.....	1
Finlanders.....	12	Portuguese.....	1

Dredge for River Mining.

(Continued from page 129.)

buckets is the subject of special improvement, whereby great discharging capacity is secured, and also great strength to withstand the charging of large quantities of material. Amalgamators, as heretofore made, have only been adapted to receive such material as could be fed to them by hand or wheelbarrow. The charge of one ton at a time, twice a minute (this being the capacity of the steam shovel) is a very different thing, and calls for different treatment, and a construction that is solid enough to withstand continuous service under such conditions.

The gold-bearing sand and gravel, after passing through the screens into the tank, tends to settle to the bottom, under the cylinder. It is prevented from doing so by jets of water issuing from small inclined nozzles in the bottom of the tank, which maintain the gold and sand in suspension, and which are so directed as to cast it repeatedly over the amalgam plates with which the tank is lined. Every particle in this way is brought a great number of times in direct contact with the plates, so that none of the gold has a chance to escape. The same jets are so directed as to have the effect of working the sand toward the rear end of the tank, from whence it escapes as tailings, through a suitable valve.

The pressure of water required for these jets is about 20 lbs. per square inch, and the quantity about 600 gallons per minute. By suitable arrangement to drain off the tailings the same water can be used over and over again, only enough of a supply being necessary to make good the losses by seepage and evaporation. The pump to furnish the pressure can be located at any convenient point.

It is proper to say that the amalgamator and dredge are designed for work on land as well as on water. The amalgamator may be placed on a separate car or other movable carriage, beside the dredge and worked in placer deposits. A steam derrick can be carried along with the steam shovel and amalgamator, to remove the tailings.

The larger of the accompanying illustrations shows one of the Bucyrus steam shovels at work in a deep cut, and illustrates the character of material that is sometimes met with. The bank in this case was over 100 ft. high, and consisted of heavy clay and large boulders, and at times it would cave down. The machine was on more than one occasion completely buried, but suffered no material injury. This machine has two cylinders, 8x12 ins., and a dipper of 1½ cu. yds. capacity. The company has manufactured nearly 200 steam shovels, varying in capacity from 200 to 3000 cu. yd. per ten hours.

The Anti-Debris Association Again.

The State Anti-Debris Association issues the following statement to the public:

"During the past six or eight months the hydraulic mines in the mountains have generally been on their good behavior for the apparent reason that they wish to curry favor with the Caminetti Debris Commissioners. But even during that period a few mines operated by Chinese have run in violation of the law and injunctions in such a clandestine manner that it has taken the time of more than one watchman to look after them and keep them in anything like obedience to the law.

"In the mean time many miners have calculated on the cost and feasibility of bringing themselves under the jurisdiction of the Debris Commissioners, and, by the appearance of the repairs they are making, are getting ready to go to work without right or permits from the Commissioners, and bid fair to give us more trouble in the future in the way of violating the injunctions.

"It is further a fact that at least two large hydraulic mines who applied to the Commissioners during the month of December, 1893, for permits, did not wait for the Commissioners to decide their cases, but deliberately went to piping under the claim that they had been granted permits, and this, too, when they knew their claim was false. This fact can be obtained from the records of the Commissioners at any time.

"The Commissioners have decided that they will not undertake to control any hydraulic mine which does not bring itself under their jurisdiction, according to the Caminetti law, and they are still in doubt as to whether it is their business or duty to attempt to punish those who have brought themselves under their jurisdiction by a surrender of their property, etc., but who nevertheless are operating in violation of the law and the injunction of the courts.

"The Debris Commissioners consist virtually of only two men who are physically able to do the field work of examining the works of these mines and looking after them, and their time is so occupied with official duties, as is the time of the entire Commission, that it is unreasonable for anybody to expect them to look after the immense hydraulic mining territory which extends from Shasta county to Calaveras county, and to prevent violations even of their own orders.

"Hence the valley property-owners are left in this condition under the Caminetti law, viz.: Where we had previously got the mines pretty well stopped by injunctions we have now a law which grants them the right to operations provided they comply with the law. That law is to be enforced by four men whose time is already fully occupied and who get no additional compensation for this work, and who cannot, therefore, get out and do the hard labor that is required for looking after these habitual violators of the law.

"Some mines will see that the new law cannot benefit them, and they will proceed to work in violation of the injunction as before,

without fear of molestation from the Debris Commissioners, using Chinamen, perhaps, as a cat paw. Other mines will go through the form of surrendering their rights to the Commissioners, and then without complying with the requirements of the Commissioners in the way of building restraining dams or works will proceed to work when the Commissioners are not looking on. Thus it is seen that the valley is under as great need to-day of a vigilant following up of this mining evil as it has been since the first heavy battles were fought. It may be asked why the United States authorities through the criminal courts do not handle these violators of the law? The answer to that is, that the United States Marshal has not funds at his command to maintain a system of watch over these mines."

This manifesto is worth noticing as testifying to the fact that the Anti-Debris Association is still alive, but that it has lost almost all the vigor and energy which formerly characterized its actions. If miners are operating in violation of the Caminetti act, why does not the Anti-Debris Association appeal to the law as it did in former years with such signal success? Why does it content itself with sitting idly by and inflicting upon the public impotent wallings over the inefficiency of the law and the weakness of the Debris Commission? Does the Anti-Debris Association expect that the Debris Commission will adopt for itself the tactics of espionage enforced in so creditable and honorable a manner for many years by the Association? Or cannot the Anti-Debris Association be trusted longer to protect its own alleged interests and report violations of law as it always has in the past?

As a matter of fact the Anti-Debris Association has exactly the same opportunities and recourse to the courts as it had in former years. It can sue out injunctions as it always could, and it is further supported by heavy penalties imposed by the Caminetti law for violation of its provisions. It is not the business of the Debris Commission to fine and imprison malefactors. That is the duty of the courts, as it has been.

The real trouble is not with the law, but with the facts as alleged by the Association. It is not denied that Chinese and other miners occasionally attempt to hydraulic under cover. They did before the Caminetti law was passed. A few were arrested and punished. Others were not molested. We do not know why. Perhaps the spies of the Anti-Debris Association can tell. The California Miners Association labored earnestly to secure observance of the law, and none regretted these occasional infractions more than its members. But we believe, and the public believes, that the provisions of the Caminetti law are pretty generally respected.

The complaint of the Anti-Debris Association is really an arraignment of the Caminetti law, and the insufficiency of restraining dams. It threshes old straw. Its cause is on the wane and it attempts to revive old prejudices against the miners. It will not succeed.

The Gold Output in South Africa for Five Years.

The following table of the gold output in South Africa during the five years ending with the year 1893 was prepared by Sir Moreton Frewen for the New York Sun. It is altogether probable from the present outlook that during the year 1894 the output will exceed any previous year by many hundreds of thousands of ounces. This statement is based on the fact that a great tract of new territory has been opened, and the mines now operating are much better developed:

MONTH.	Oz. 1889.	Oz. 1890.	Oz. 1891.	Oz. 1892.	Oz. 1893.
January.....	24,985	35,030	53,205	84,550	108,370

Slitkens.

The Mercur mine of Utah paid a dividend of \$25,000 on March 1st.

A Los Angeles drug firm has bonded the Stevens borax mine at Calico for \$50,000.

HAVERV HARRIS, a well-known pioneer and metallurgist, has died at Gold Hill, Nev.

ALL the mines in Grass Valley district are regulated by the standard time of the Western Union Company.

The Omaha Mining Company has declared a dividend of 15 cents per share, which is now payable. The mine continues to look well.

ANOTHER very rich pocket has been struck in one of the Bonanza Company's mines at Harqua Hala, that is said to be richer than anything ever encountered before.

The Standard Mining Company has been organized at Tacoma, Wash. Capital stock, \$5000; 5000 shares of \$1 each. Incorporators—E. F. Cadwell, Starr Sherman and J. H. Ortman.

RICH gold quartz has been taken from the bottom of the must condenser well at Healdsburg, which had been broken in a blast. The well is 200 feet deep, and no water has yet been

obtained. The quartz will assay \$200 to the pound. The strike has caused much excitement. The bore of the well penetrates the gravel deposit along the Russian river.

THE Iron Mountain and Moulton mines of Montana both paid the usual monthly dividends in February. Some silver mines can make money even at the current low prices for that metal.

THE mines in the mountains have been very much hindered in their work by the water. Heavy rains and melting snow have caused the lower workings of many properties to be flooded.

SINCE the Leavenworth, Wash., mining district was organized, no less than 225 placer claims have been located on the Wenatchee river, above and below Leavenworth, and interest increases.

FRANK ZATTONI, formerly in the employ of the Oregon Improvement Company, has commenced suit at Seattle against the company for \$200,000 for injuries received while at work in a coal mine.

THE Coquille Coal Company has been organized at Coquille City, Oregon. Capital stock, \$4000; 160 shares of \$25 each. Directors—A. A. Leach, J. C. Wilson, Will Price, Will Barrows and Albert Wilson.

THE Canyon Creek Placer Mining Company has been organized at Spokane, Wash. Capital stock, \$250,000; 250,000 shares at \$1 each. Incorporators—John F. Wolgamot, Perry Griffith and Frank T. McCullough.

THE New Issue Gold Mining Company has been organized at Seattle, Wash. Capital stock, \$2,000,000; 200,000 shares of \$10 each. Incorporators—L. L. Johnson, Wm. C. Keith, J. A. Helman and Frank B. Ingersoll.

DUEING the past few days several thousand dollars have been taken out of the pocket mines at Sonora belonging to the Obenoweth boys, Terzich and Stewart Miller, and some have been found in several other pocket veins.

THE stockholders of the Minnie Quartz Mining Company will hold a meeting on April 27th to increase the amount of capital stock from \$300,000 to \$600,000. The company has also levied an assessment of one-half cent per share.

FOUR HUNDRED coal miners employed at Lethbridge, Mont., have struck. The cause of the trouble was several reductions in the wages by the company. Serious consequences are liable to follow, as Lethbridge has a population of 1500 dependent on the mines for support.

THE United Verde Co.'s works at Jerome, Ariz., says the Prospector, are making heavy cuts in wages and otherwise curtailing expenses. All surface men have been cut from \$2.50 to \$2.25 per day; machine men in the mine from \$4 to \$3.50; carmen in the mine, \$2.75 to \$2.50. A strike is expected.

PRIVATE telegrams from Washington announce the sudden death of Spruille Baden, a brilliant and successful mining engineer. He was for years United States Assayer at Helena, Mont., and one of the best contemporaneous authorities on silver, gold and copper ores of the Rocky mountain region.

THE Flagstaff Mining Company is the name of the latest incorporated company for Fergusson district, organized under the laws of Nevada. The properties incorporated embrace the Flagstaff, Apex and the Boss locations, on which work has been going on for six months past with flattering results.

THE employees on the day shift at the Union mine, Austin, Nev., all quit work recently. The miners wanted to take only half an hour for dinner and quit at half past five. The foreman said his orders were that the miners take an hour for dinner and quit at six o'clock. The order did not suit the miners.

TWELVE YEARS ago, Richard Hicks of Hills Flat was blasted in a mine, says the Grass Valley Telegraph. At that time a rock lodged in his thigh, which caused him but little pain until very recently. Suddenly it became inflamed and very annoying, and the thigh was cut open by Dr. Jones and the rock taken out. Mr. Hicks never knew that the rock was in his thigh, but now that it is removed he feels much easier.

THE Transvaal mine of South Africa is said to be one of the largest subterranean gold mines in the world. There are 4½ miles of drives underground along the reefs. Three vertical shafts of 400 feet have been sunk, and the fourth, fifth and sixth levels are well developed. The ore is low grade, but there is plenty of it. There are 400,000 tons of ore ready for milling, enough to keep all the stamps in full operation for 12 months.

THE property of the Albany Mining and Milling Company, in the Santiam district, has been sold to Thomas C. Drew, owner of the Hammersly mine, and C. G. Clark for \$140,000. The mine, which is of low grade gold and has been developed since 1860, comprises 13 claims and has 3500 feet of tunneling. The plant will be doubled and chlorination works added. The purchasers say there is enough ore in sight to keep ten stamps running ten years.

THE De Beers Consolidated Mines Company has made another good year's record. For the year ending June 30, 1893, it realized £3,239,389 from the sale of diamonds produced, £99,426 from dividends on investments and £11,717 from miscellaneous sources. It paid £1,695,293 for interest on debentures, etc., and £987,238 in dividends to stockholders, equal to 25 per cent. It could have paid much more. The property on July 1, 1893, was in a better condition than at the beginning of the previous year.

THE largest nugget found in Shasta county in many years was picked up on February 21st by S. Elmore, on his gravel claim near Copley, says the Free Press. The nugget is about five inches long by two and a half inches wide, shaped much like an egg, weighs 30 ounces and is valued at \$520. Mr. Elmore is an old pioneer and miner, and formerly owned the ranch near Elmore, the railroad station named after him. W. W. Williams, the groceryman, has purchased the nugget and will ship it to the mint for coinage.

THERE are at present in the mining districts near Yuma, eight quartz mills having a combined capacity of 150 stamps, says the Times. Thirty stamps are not quite ready to drop and three mills, of 10 stamps each, are idle. The remaining 90 stamps are all running on gold of varying richness. The product will probably average \$100,000 per month. In addition to this, the product of the silver-lead districts is from \$10,000 to \$15,000 per month. The number of men employed in and around the mines and mills is about 500.

One More Reply to Mr. Chapman.

TO THE EDITOR:—In a recent number of your paper appeared an article written by Mr. W. S. Chapman. Will you kindly allow me to give the views of a practical miner in reply? Mr. Chapman's article may be divided into seven heads, viz.: (1) Changes in Mining; (2) What to Do; (3) Sulphurets; (4) Economy; (5) Living; (6) Gambling in Mines; and, (7) Knowledge of Mining.

First, Mr. Chapman advises different management, and, instead of spending from \$50,000 to \$250,000 in a mill, would put from \$400,000 to \$600,000 in a hole in the ground, with its attendant levels, etc. Now, if Mr. Chapman fails to find his mine, what is best? In my opinion, and also the opinion of most miners, the best thing to do is to first sink on your vein, and, as fast as you find sufficient ore to justify a five-stamp mill, put it up; keep on sinking, and, when you can afford it, add five more, etc. When you get down 1000 feet, and you have a mine, sink your double perpendicular shaft and use your old one for air escape, etc. This is legitimate mining; but, if you sink 1000 feet and fail, you have been a victim of chance, and some one is hurt. So much for the first two heads. Now for

Sulphurets.—Mr. Chapman admits that the pioneer miners failed to save sulphurets; and, because evolution has taught us that which they could not know, they are to be blamed. Those very failures made the mines of to-day. Our fathers experimented and we profited by their discoveries. Many miners have failed because they did not know how to reduce the rebellious ore. The mills were all right. They ground the rock as fine and as quickly as we can to-day, but they could not get the dust because they at that time did not know how.

Economy.—Mr. Chapman says: "Mines must be more economically worked than they have been. There is no reason why wages should remain as high as they are. While I am not in favor of reducing workmen's wages as a rule, yet I think it would be far better for the unemployed to work in the mines for \$2 a day than to be seeking work in the park, or around the city, or any place where they may procure work at \$1 a day, and most of the time having nothing to do at all." Hear this philosopher! Mining is a scientific pursuit, and every person is not qualified to mine, any more than every man who can hit a nail is a carpenter or builder. I was born in Tuolumne county in 1857, and have followed mining all my life, and am not ashamed to say that I have much to learn in my chosen profession. It does seem strange that economists on mining every little while attack the profession that is the worst paid (considering the danger) of any. The poor unfortunate miner must risk his life every day; must inhale noxious and poisonous gases; must, in some cases, work under a man who received his mining education in some city—one, perhaps, who would call a piece of old pumpkin flint spar, or who will, with the greatest equanimity, carry a piece of grindstone to the assayer—and, after all this, he is classed with the rabble who must work, poor fellows, for what they can get.

Living.—Mr. Chapman claims that people can live as cheap in California as anywhere. This may be true of the city or large railroad towns, but mines are rarely found in cities. Mr. Chapman himself says that after the prospector has found his mine in the mountains (and I suppose dug his 1000-foot pit) that capital may not come to his relief. As a general thing, the freight on goods costs the miner more than the purchase price in the cities. In summer you can purchase potatoes in San Francisco or Sacramento for 50 cents per sack. The freight from Auburn here is 50 cents per hundred in summer and 90 cents now, a distance of 16 miles. Take Tuolumne, Amador, Nevada, El Dorado, Calaveras and Mariposa, and freight is all the way from 45 cents to \$1 and \$1.25 to the various mining camps. This leaves skill out of the consideration. To equalize things would entitle the miner to more wages than his city brother. But he does not get it. To be a miner a man must spend more time than to become a carpenter, blacksmith or bricklayer. Did you ever hear of these tradesmen working for \$2 a day? That is what they get here. I am informed that the largest mine here, to their shame be it said, have taken advantage of the hard times to cut the wages to \$2; and that, too, in a mine that is supposed to be slowly coming together.

Gambling.—Mining, Mr. Chapman says, is not gambling, and I agree with him this far, that it is not gambling when honestly conducted. Like any other business, it can be made to pay as it goes along. But when you dig long levels and 1500-foot pits (and perhaps fail) it might be classed as chance.

Knowledge.—Mr. Chapman is right. We need knowledge, more knowledge of mining; first, the men who put up the money, and, secondly, you and I. The first thing for capital to do is to employ a practical miner to be superintendent, even if they have to employ a clerk to keep his

books. They will find that he will know whom to employ, and they will also find that their mines will not cave. He may not be able to talk geology and write foolish letters, but can tell gold and silver-bearing ore from grindstone when he sees it. If Mr. Chapman will come up here and pick in the gulches around Georgetown awhile, as I have done all winter, I can assure him, as he eats his beans and hears his bacon sizzle, that he will be gaining something I believe he is much in need of.

JAMES BOGAN.

Georgetown, El Dorado Co., Cal., Feb. 25, 1894.

Mountain Mines—Tuolumne County.

TO THE EDITOR:—The following mines are situated in the Soulsbyville mining district and have all yielded considerable gold in years gone by. Some of them are only worked to shallow depth, and as there is some water in the mines, small pumps and machinery will now be required to open them. The owners have no money.

First is the Soulsby mine owned by Messrs. Sherwood & Leechman. It consists of two claims of 3000 feet in length. It is in granite formation and is now idle. It has been opened by three shafts; the north shaft is 600 or 700 feet in depth, and the south shaft, which is several hundred feet from the north shaft, is 800 or 900 feet in depth and have been connected by drifts. There were several chutes in this mine and the ore taken out was of a high grade. Several millions have already been taken out of the famous Soulsby and there is a large amount of gold yet in the mine. The improvements consist of a 15-stamp mill, hoisting works, etc., which are operated with water power with a fall vertically of about 300 feet. There are also blacksmith shops, boarding house and other necessary buildings connected with the mine.

The Northern Belle mine is to the north of and on the same vein as the last mentioned mine, and has not been opened since it was first worked in early days—and ore taken out at that time yielded \$20 per ton. It has only been worked to shallow depth.

The Mountain Belle mine is still to the north of the last mentioned mine. It has been opened by two shafts, the north shaft 100 feet and the south shaft 80 feet in depth. Both shafts are connected by drifts. Ore from this mine when last worked yielded \$70 per ton. The sulphurets are of a high grade and there is a good percentage of them.

The Tuolumne, which was discovered and first worked in the early sixties, is thought to be a good property. All ore has been stoped out about 75 feet in depth and was of a very high grade. The sulphurets were not saved but the assay value was \$300 and upward per ton. The vein in the bottom of the shaft is of a small size but the last ore taken out paid \$125 per ton in free gold. The size of the vein runs from 6 to 18 inches in width, granite formation. Pump and hoist will now be required to open this mine, and by sinking the shaft no doubt large bodies of high grade ore will be opened up.

An old ancient river or channel runs near Soulsbyville. A shaft has been sunk to the depth of 90 feet, which was to the north of the main channel. A drift was started, but as the owners had no capital they had to close down before the channel was reached. They had small prospects and are now fully convinced that it is a large channel, and no doubt contains a great quantity of gold. It can be traced for miles and can be fully prospected for a few hundred dollars. Good water power can be had and free water during the winter months. We hope this property will soon be opened, and when it is, it will make busy times in this section of the country, as we are fully convinced that there are large quantities of gold in this channel.

MINER.

A Steam Hydraulic Plant.

TO THE EDITOR:—Yesterday was a gala day for the people of this place. It was the occasion of the breaking ground, so to speak, of the mammoth steam hydraulic mining plant that has been placed on the Hadley bar, two miles below town. This plant has been in course of construction for over a month, and yesterday steam was gotten up and the water turned on the gravel with a force that made the boulders dance like fairies.

This bar lies along the South Umpqua river and was first worked in the early fifties, a little over an ounce of dust being taken out by three men in one day by the old process of wheeling the dirt and washing it in one sluice box. But owing to the lightness of the gold (thin scales) the old process cannot be used except during extreme low water, when there are a few spots that can be profitably worked in this manner. This bar has been prospected by numerous parties at various times, nearly every one of whom pronounced the bar very rich and likely to be good property, provided a process could be used that would successfully save the gold. About a year ago Mr. Coburn, an old forty-niner, came to this section of country, and, after thor-

oughly prospecting this bar, became convinced that it could be successfully worked by means of a steam hydraulic plant, and what he terms the "burlap process." The general contour of the ground and the fall in the river made it impractical to attempt taking out a ditch for this purpose. He then proceeded to lay his plans before White & Co. of Tacoma, Wash. These gentlemen, after an examination of the ground, proceeded to buy up all the land on which this bar was deposited, and also to locate a number of claims. They then procured a 150-horse-power boiler and a No. 15 Gardner steam pump, having a maximum capacity of nearly 100,000 gallons per hour, with a 10-inch suction and an 8-inch delivery pipe. This pump has been warranted to throw a cutting stream 100 feet through a 2½-inch nozzle.

The machinery all started off smoothly, and the only thing remaining now is to await the result of the first clean-up, and then we will see how the "burlap" process works. If it saves the gold successfully there will be half a dozen similar plants put in operation during the year, for there are thousands of acres along the river equally as good if not better than the Hadley bar.

W. T. FOGLE.

Myrtle Creek, Or., Feb. 26, 1894.

To Make Non-Flowing Wells Flow.

The Chapman Patent Process is designed to cause non-flowing wells to flow without pumping. Its claims are as follows: It will deliver from two to five times more water than can be pumped, and is more economical than any other means of raising large quantities of water. No well is too small, too deep, too large, the water too muddy or too sandy for the use of this invention.

We here illustrate a new principle of causing artesian wells to flow. It consists of placing an air pipe connected with an air compressor a suitable distance down into the well, with an ejector placed on the lower end of the air pipe and a separator on the top. The air is forced down into the well and expands upward out of the ejector with great velocity, carrying the water with its force and expansion. The air being so much lighter than the water, the difference in their gravity assists to cause the water to flow over the top of the well with great velocity. It will throw out sand and gravel without injury to the machinery, and when there are obnoxious gases in the well, such as sulphurous hydrogen or other gases that will mix with the air, they will leave the water in the separator; and when the air is cool at the compressor, before being forced down, the air as it expands will absorb the heat in the water and make it much cooler and more potable. It is suitable for irrigation, water works, ice plants, breweries and all places where large quantities of water are required. The manufacturers guarantee this invention to give satisfaction, or ask no pay for the erection of the plant.

Further information will be furnished by addressing the American Well Works, Anrora, Ill., Chicago, Ill., or Dallas, Tex.

THE profits of the Alaska-Treadwell mine for the six months ending Nov. 30, 1893, were \$283,179.23. The above sum of \$283,179.23 does not include store profits for the period. Allowing usual rate of income from this source, the profit made for the six months, and available for distribution, has been say \$288,000; the regular dividends have absorbed \$150,000, thus leaving \$138,000 surplus on account of the bonus dividend to be declared in May, 1894. The bullion output and net profit have both been higher than for any previous half year in the history of the mine; while the total costs of \$1.25 per ton (less than 1½ dwts.) have been lower than ever before. The ratio of net cash profit to bullion output, therefore, shows the very satisfactory figure of 66 per cent. The Treadwell mine to Nov. 30, 1893, has produced \$3,838,076.30 of gold, with a net profit of \$2,528,802.85.

THERE is good authority for the statement that the Senate committee on the tariff bill has decided on a small duty on lead ore and coal, and that iron will remain free as in the House bill. Sugar still hangs in the balance, the prevailing opinion being that a compromise duty of three-quarters of a cent per pound will be reported.

THE CLAYTON AIR COMPRESSOR WORKS have removed their offices and salesrooms to the second floor of the Havemeyer Building, 26 Cortlandt St., New York, retaining their former store as a warehouse. We wish the Clayton Works every success in their new and commodious quarters, and trust the volume of their business may even exceed that of former years.

Limitations of the Gold Stamp Mill.

Discussion by Phillip Argall, of Denver, Col., on paper read by T. A. Rickard before the International Engineering Congress.

The limitations of the gold stamp mill resolve themselves (according to Mr. Rickard) into the slow speed, long drop and high discharge, represented by the Gilpin county practice on the one side, and the fast speed, short drop and low discharge represented by the California practice on the other; while in the contrast between these systems he illustrates the very elementary axiom "that the treatment must be suited to the character of the ore." On this latter point, at least, we can all agree.

The high discharge is invariably used where fine crush-log is desirable, or where stamping and pulverizing in one operation are necessary for the liberation of the fine gold. This practice is not by any means limited to Gilpin county or to any recent dates. As early as 1868 mills were running in Victoria, Australia, with drops of 18, 16 and 15 inches, the number of drops varying from 35 per minute upward, and the weight of the stamp from 300 to 900 pounds.

At the Morro Velho mine, Brazil, the high discharge has long been used in the treatment of pyritic ores. Some carefully conducted experiments with high and low discharge at this mine are given by Mr. J. A. Phillips, and are well worth quoting:

"With a 6-inch discharge, 75 per cent of the stamped ore passed through a 120-mesh screen, and the loss in gold amounted to 44.70 per cent, while with a 20-inch discharge, 87.5 per cent passed through a 120-mesh screen, the gold loss being only 30.96 per cent. In other words, the high discharge reduced the material retained on a 120-mesh screen 15½ per cent, and thereby increased the gold saving 13¾ per cent.

It is a well-established rule that fast speed, short drop, low discharge and heavy stamps are to be used for coarse crushing, while for fine crushing, slow speed, long drop, high discharge and light stamps are in order. The point at which fine stamping should cease, and from which the further pulverization of the ores should be conducted in Chilian or Hungarian mills, arrastras or similar pulverizers, is not, however, very clearly defined.

The stamp is a very inefficient pulverizer, at best, and were it possible to get on the die at any one time all the fine particles requiring further reduction, the philosophy of lifting a 500-pound stamp 20 inches to crush these minute particles of ore is not very apparent. Mr. Rickard claims that the turning of the shoe causes the abrasion of the surface of the gold, etc. This action is, I believe, so insignificant in the stamp battery as to be almost unworthy of notice; and hence, when the grinding or abrading action is necessary to prepare the gold for amalgamation, resort is usually had to arrastras and similar grinding machines. This has been well illustrated at the Pestarina mine, Italy, where the best possible extraction with stamps did not exceed 65 per cent, while arrastras, in the form of the Frankfort mill, gave an extraction of 82 per cent. The ores were principally iron pyrites, carrying the gold in minute particles, more or less infilled in micaceous schist. Not only fine grinding, but also time and attrition, were found necessary for successful amalgamation.

Among the advantages claimed for the Gilpin county mills, we find the following:

(1.) "The deep discharge causes the pyrites to remain in the mortar long after it has been pulverized to a size smaller than the screen openings." Now, it is manifest that if the pyrites remained longer in the mortar than the other portions of the ores, the mortars would eventually be filled with pyrites to the depth of the feed used. This condition of affairs is not found to occur in practice. As I understand it, all the ores are retained longer in a deep mortar than in a shallow one; they are, therefore, crushed finer, and consequently the friable ores are reduced to an extremely fine state of division, and in great part converted into slime.

(2.) "The long drop gives the interval of time required to allow the settling of the fine gold." The coarse gold, in all probability, settles in the mortar and is amalgamated; the fine gold, however, would be thrown upward by the splash, and caught in part on the copper plates, and in part discharged through the screens.

(3.) "The roomy character of the mortar aids the deep discharge in affording a chance for the gold to get out of the way of the falling stamp, and to become amalgamated on the copper plates." It is difficult to comprehend how the roomy character of the mortar or the deep discharge can either jointly or severally afford a chance for the gold to "get out of the way" of the falling stamp, unless on the hypothesis that the gold is endowed with the potentiality of locomotion.

Mr. Rickard believes that the hammering which gold receives in a stamp-battery prevents amalgamation.

Professor Egleston says that hammering gold on a

smooth anvil with a clean, smooth hammer prevented amalgamation; and he has further proved that hammering gold in a clean mortar, under water, also prevented amalgamation. It is important to note that, in both examples, gold was hammered between smooth iron surfaces, an action that never occurs in a stamp battery, in which the gold, if hammered at all, receives the pounding between rough and gritty ore, or, at most, against but one iron surface, the result being the roughening and cutting of the gold flakes and particles, thus presenting new and clean surfaces to the mercury and assisting the amalgamation.

Indeed, Prof. Egleston's experiments confirm this view, for he found that when a freshly broken edge of the gold plates came in contact with mercury, in every case it amalgamated at once. I have never found hammered unamalgamated gold in stamp-mill mortars where mercury was used, nor have I ever found a millman who has noticed such an occurrence. I am therefore warranted in the conclusion that the hammering (?) which gold receives in a stamp battery does not prevent amalgamation. On the contrary, I think it has a beneficial effect on that process.

We are told that the metallic sulphides commonly occurring in gold ores will be found, after stamping, in thin flakes and plates which readily float upon a running stream. These sulphides are iron, copper and arsenical pyrites, zincblende and galena, and I am not aware that they ever break up into plates and flakes under the conditions named; they are, however, carried in a slingshot stream, floating, as it were, but simply on account of their excessive fineness.

The action claimed for the air in floating the slime in a mortar is, I presume, applicable to the California as well as to the Gilpin county mortar, if, indeed, it has any application at all. Now, the only way that air can reduce the specific gravity of finely crushed ore is by adhering in a fine film to the surface of the particles; and as the ore is wet from the moment it is put into the battery (and usually before it is put in) no air-film can form around the particles; therefore it is highly improbable that air gives the result claimed for it. As regards the heating of the water and air in a mortar, it must, under ordinary working conditions, be infinitesimal, probably not one-tenth degree F. Of the many so-called contradictory features discovered in the stamp-mill, I will note but one:

The vibration set up by the falling stamps is said to crystallize the work of the mill and assist the work of gravity on the tables. I can see nothing extraordinary in this. Vibration, under all conditions, will crystallize iron, and whatever good effect the vibration of the mill framework may have on the tables, it is not the same effect as the action of a jig.

The principal reason why the Gilpin county mill crushes less than the California is that it does more work because it crushes finer, and that, as the agitation of the water is less, the ore is not discharged so freely. The loss in efficiency due to the greater depth of water is caused only by the resistance of the stamp in passing through it, and not to the loss of weight, for this latter is the same when it is lifted as when it falls.

Pause, during which the particles can settle, is counted by Mr. Rickard as the time between the successive drops of each stamp, that is $\frac{60}{30} = 2$ seconds, but there is, in a 5-stamp set, a drop every $\frac{60}{5 \times 30} = 0.4$ seconds; consequently the water in the mortar is agitated by 150 drops per minute; the only real pause at each stamp is the fraction of a second that it rests on the ore.

In comparing the amount of water used, it should be calculated per ton of material crushed. On this basis there is no difference between the Australian and Colorado stamps; the former crushes 2½ tons with 5 gallons, the Colorado 1 ton with 2 gallons.

The greatest defect in the stamp-mill as a crushing machine is in the discharge. The ore, even with a double issue, cannot escape from the mortars as fast as it is reduced to a fineness corresponding to the screen openings, and it is consequently slim. Particularly is this the case with pyrites and other heavy and friable minerals. This defect is augmented by the high discharge used in the Gilpin county mills, and is claimed by Mr. Rickard to be made "an assistant to the millman." Now, if the greater part of the value were extracted from the pyrites, so that the tailings from the mills might run to waste, this practice would undoubtedly be the correct one to pursue; but, inasmuch as the tailings are invariably concentrated, with a view to extract this very pyrite already reduced, in great part, to extremely fine slime, it is self-evident that "the millman's assistant" in the first operation becomes his adversary in the second.

There is always a danger in comparisons and generalizations. I therefore prefer discussing specifically milling

under the conditions that obtain in Gilpin county, and to this end it is obvious that one must take the whole process into consideration. Gilpin county milling is, in brief, fine stamping and amalgamating (very fully and clearly described in Mr. Rickard's paper), followed by concentration and smelting of the concentrated product. My experience is but that of an occasional customer of the mill. As such I find the saving by amalgamation does not exceed 60 per cent on average ores; and I freely admit that this is a good saving from ores carrying their principal values in pyrites. This statement of saving is confirmed by carload lots that have been sampled at public samplers and afterward shipped to the mills for treatment, the complete returns of which I have had the privilege of examining, from time to time, as the tests were made. On straight iron pyrites, however, the saving by amalgamation in Gilpin county mills will not exceed 35 per cent of the gold, as the following tests will show.

For the purpose of testing the extraction that could be made from pyrites, I had a carefully sorted lot of 11 tons put through a sampling mill, with the result that it assayed, gold, 1.06 ounces; silver, 1.74 ounces per ton. The ore was then shipped to one of the best mills in Black Hawk, Gilpin county, and the following result was obtained:

	Weight, ounces.	Percentage saved.
Gold saved.....	4.03	34.99
By amalgamation.....	1.52	13.04
In blanket tailings.....	1.36	27.10
In concentrates.....	8.76	75.13
Totals.....	8.76	75.13
Silver saved.....	1.14	6.0
By amalgamation.....	1.52	7.9
In blanket tailings.....	7.14	37.3
In concentrates.....	9.80	61.2
Totals.....	9.80	61.2
Weight of blanket tailings.....	416 Pounds.	Gold, ozs. 7.30
Weight of concentrates.....	10,100 containing	62 Silver, ozs. 1.40
Totals.....	10,616	7.92 8.70

The gold might be described as fairly coarse. A few colors could be obtained from almost every panning. The amount of gangue in the pyrites was about 5 per cent, leaving, say, 10.45 tons of pure straight pyrites. It will be noted, however, that about 50 per cent of this was lost in the tailings, together with 25 per cent of the gold and 49 per cent of the silver, while the 50 per cent saved as concentrates contained 40 per cent of the entire gold and 45 per cent of the silver in the original ore. The concentration of the tailings in the Gilpin county mills is conducted on end-percussion tables (hump-tables). Now, as we have seen that much of the pyrites is reduced to slime in the mortars, the loss in concentration is necessarily heavy. It varies, perhaps, from 25 to 50 per cent of the pyrites contained in the ore. Some of the Gilpin county gold ores contain a fair amount of silver, the greater part of which is lost in the milling process.

The concentrates produced from the Gilpin county mills find a ready market at the Denver smelters, where the gold and silver are paid for at market rates, less five per cent, with a very moderate working charge, varying from \$4 to \$5 per ton.

It will be seen that, as the pyrites in the tailings are invariably concentrated and sold to the smelters, there is no gain in taking out part of its contained gold by amalgamation, more especially as in doing so the ore is reduced to such a fine state of division that considerable loss is entailed in the subsequent process, a loss that far exceeds any advantage derived from extracting part of the gold in the mortars and receiving the full market price for the gold so extracted. It appears, therefore, that concentration before amalgamation is the correct method to pursue in dealing with the average Gilpin county ores; and, in this connection, it is worth noting that this method is pursued in dealing with the very coarse ores from which the more or less solid sulphides are invariably picked out by hand and shipped direct to the smelters. It goes without saying that if the principle is correct in the one case it must be in the other; and if concentration by hand is applicable to pieces of ore from, say one-inch cube upward, mechanical concentration is equally applicable to the finer portion of the ore, as also to the fixed ores that require crushing preparatory to concentration.

I am fully aware that, in advancing the doctrine of concentration before amalgamation, I am going over old ground; nevertheless, I hold that it is the correct method to pursue, and, as such, cannot be set aside on account of the failure of previous crude tests, which were faulty in execution and incorrect in principle. Smelting is a very important step in the treatment of Gilpin county ores; without it the present system of milling would cut but a sorry figure in the metallurgy of the West.

The full importance of smelting does not appear to be thoroughly understood by the mill-owners, and it is not to be wondered at that the full advantage to be derived from concentrating and smelting is neither admitted or practiced.

Quartz Belt of Butte County.

Abridged from article in Oroville Register.

The quartz belt of Butte county is attracting more attention than ever before in the history of this State. The mining developments have been rapid and of great extent during the past two years, and some details concerning the veins of gold found in this county may be of general interest.

Two-thirds of the 1,200,000 acres of Butte lie in the foothills and mountains, and these hills and mountains are seamed with veins of gold-bearing quartz, which in by-gone times fed the hundreds of rich placer mines that made this county famous in the days of pioneer mining. In addition to the number of veins being worked at present, there are many others which are being prospected, and thousands of additional ones on land owned by the Government or by the Southern Pacific Company. These will some day be prospected, developed and worked, for gold-bearing quartz will be mined and milled in California when more years will have elapsed than the number passed since America was discovered. At an early day in this county, quartz veins containing gold attracted the attention of miners, and a few small mills were erected; but owing to the high price of freight, machinery, supplies and labor, it took rock that was exceedingly rich to pay expenses. Amid the foothills of the county there are hundreds of old tunnels that were run on ledges where the miners hoped to strike rich pockets, as ordinary quartz could not afford to be crushed.

After the first great rush of mining was over, quartz mining declined in Butte and did not revive until within a few years, when much prospecting was done, many mills erected and hundreds of thousands of dollars were invested in mining property. Many things contributed to the rapid extension of quartz mining during the past few years. In the earlier or primitive mining the ledges that were sulphuretted were avoided, as the miners did not have appliances to successfully work the ore. This class of lodes is more numerous in Butte than those containing free gold only, so that at present the ledges are in demand that in former years were passed by, for the lodes that are heavily sulphuretted are those which pay best for working. Under the present methods, there is but little trouble in saving a large percentage of the gold, whereas in earlier times much of the gold was lost. In a single ravine, old miners point out tallings that it is said contained \$200,000 worth of gold that was lost owing to a lack of facilities in saving the light or floating gold which passed through the concentrators.

While there are numerous mills in Butte county crushing ore, and many lodes being prospected, yet we consider quartz mining in the county only in its infancy, for so numerous are quartz ledges that we doubt if a single section of mountain land about Forbestown, Hurlston, Bangor, Wyandotte, Enterprise, Lumpkin, Oregon City, Nimshew, Magalla, Lovelock, Inskip, Cherokee or Deadwood can be found without one or more lodes containing gold.

Three hundred and fifty Ledges.—The quartz belt of Butte begins in the foothills at an altitude of about 500 feet and extends to the top of the highest mountains fully 6000 feet high. Among the lodes in the low foothills are the Mascot, Standard and Banner. From the latter \$600,000 was taken out in a short time. These are near Oregon gulch and Oregon City. Close to Oroville are two lodes being developed by G. M. Sparks and G. Strang and by Miller, Ordway & Co. There are several ledges near Wyandotte and others near Bangor. One there is owned by Gardner Osgood and another by Parks & English. So rich is the latter lode that this winter, while working the rock, the men were armed with Winchester rifles and no one was allowed to come near unless his name and business were known to the owners.

The region about Hurlston where the altitude is from 1500 to 1800 feet, is ribbed and seamed with veins of quartz which are rich in gold. Here the Phoenix, Pactolian, Stow or Dutch Ravine, Hurlston and Chevalier ledges are being developed, together with many others that are being prospected. W. W. McMillian, Jr., who is recognized as one of the best prospectors in the county, estimates that there are not less than 250 lodes within a few miles of Hurlston which in time will prove profitable. Capital is needed to open and prospect these, to ascertain their extent and to place mills where the rock can be worked in a cheap and in an economical manner. The locality known as Enterprise, on the South Fork of Feather river, contains numerous good ledges. Some of these, as the Oro and E. W., have been successfully and profitably worked, and others are now being opened. Near here is one of the grandest ledges in the State. It is owned by Jas. Carlisle, but for several years has been in litigation. The ledge is very wide and can be traced for a long distance. Miners who have lived long in the locality believe there are not less than 50 ledges near that will pay to work. To these we may add the same number for Bangor, making for the

three localities no less than 350 ledges. It is about 12 miles from Enterprise to Bangor, and the whole mass of hills appear to be crossed and recrossed with veins of gold-bearing quartz.

Richest District in Butte.—The section named above is, however, only the lower edge of a vast quartz belt which extends up to Forbestown and Mt. Hope, and this is known to be the richest quartz belt of the county.

The mass of mineral about Forbestown is the largest and richest so far opened in the county, and the developments now made warrant the assertion that Forbestown will be a thriving and populous mining town for many years to come. The Goldbank, Shakespeare, Golden Queen, Denver, Bullion, Mount Hope and other mines and mills in this vicinity have a large number of men employed. The reduction works of the Shakespeare and Goldbank mills are the largest in northern California, and several new devices have been introduced for the purpose of saving all the gold in the quartz. It is entirely within bounds to say that within a few miles of Forbestown not less than 100 quartz lodes have been located and some work done to develop them.

Another Rich Locality.—Oregon City, Oregon gulch and Morris ravine, all within a few miles of each other and within seven or eight miles of Oroville, are rich in gold-bearing quartz. Here are located the Banner, Mascot and Standard quartz mills and here many ledges have been prospected. In early times there were some extremely rich ledges worked here, and now several of these are being reopened. County Surveyor McCoy, who has been carefully over the ground many times, estimates that in the township there are not less than 75 lodes that will prove valuable for mining.

He estimates the same number in the township in which Yankee Hill and Deadwood are situated, and in which are situated the Rainbow, Wellington, Eagle Point, Jordan Hill, Paxton, Porter, Brnwell, North, Christie and 14 claims located by W. T. Coleman. The townships together he estimates to contain 150 gold-bearing veins that will pay to work. Now if to these we add the 100 at Forbestown, 150 at Enterprise and Bangor and 250 about Hurlston, we have 650 ledges that competent men estimate will some day be worked for the gold they contain. There are many other parts of the county rich in quartz, namely, Lumpkin, Brush Creek, Lovelock, Magalla and Inskip, and all these contain good paying lodes. The western line of the extensive quartz belt in Butte is considered to be Butte creek, but there are excellent lodes west of that stream. C. W. Russell, a miner of many years experience, says the region about Inskip and Lovelock is seamed with gold-bearing veins which in the future will prove a source of immense wealth. Capital is needed in Butte to develop many of the mines, as it is but a few years since quartz-mining began here on an extended scale, and the county suffers from a lack of capital to open some of the best mines it contains.

Opportunities.—There are many opportunities here for those desiring to invest mining capital or who seek to secure valuable deposits. Of the thousand gold-bearing veins in the county, not 100 have been mined. There are thousands of acres owned by the Government and by the railroad company that can be purchased for nominal figures, and these lands in many instances are rich in quartz. This country lies upon the western slope of the Sierras where the climate is not severe and where water and wood are abundant. There are hundreds of streams from which water can be easily obtained for cheaply working arrastras or stamps. Snow does not fall deeply until you reach an altitude of 4000 feet, and it therefore rarely interferes with mining. The hundreds of creeks and canyons of this county were among the richest in California and the gold originally came from quartz ledges.

The Snow Sheds.

During the last storm snow fell as far west as Auburn, Cal., which is something unusual, says the Winnemucca *Silver State*. At Towle's station, east of Alta, there was a fall of fifteen inches. On the summit six feet were piled up, which makes the total depth about fourteen feet. The snow galleries along the line of the Central Pacific are completely shut out from daylight for several miles west of the summit of the Sierra range, and without them there would be no possibility of keeping the line clear for travel with the present depth.

These galleries cover the track the entire length of the snow belt—a distance of forty-five miles, extending in an almost unbroken line from a short distance west of Truckee to Shady Run station, four miles east of Alta. A pine forest, with an area of over ten square miles, was felled to furnish timber for their construction.

The cost per mile of these structures was \$46,000, except across the summit, where three miles of the galleries cost \$96,000 per mile. These galleries are built of huge timbers

bolted to the granite rocks, and are of a strength sufficient to withstand the shock of the avalanches that sweep over them when the snow begins melting in the spring. In descent to the bottom of the deep ravines below these avalanches sweep everything in their path, lofty pines that have withstood the storms of centuries being carried along with the moving mass. When the project of erecting these snow galleries was first suggested it was declared impracticable, but without them traffic would be suspended nearly every winter over that part of the snow belt protected by them.

The Coolgardie Fields.

As our knowledge of the gold fields of West Australia accumulates, it is very evident that impressions and opinions formed a few months ago must submit to modification, says the Australian *Mining Standard*. The glowing and exaggerated reports received from Coolgardie, for instance, in the throes of the excitement attendant upon the discovery of Bayley's, in the light of later information will not hold water, nor are they any longer viewed with reliance. At the same time, it must be admitted on all hands that Coolgardie and the Murchison are remarkably rich auriferous areas, the like of which was before unknown in Australia; and which, if developed with calm judgment, and the constant idea that mining is an industry and not a speculative pursuit, will largely assist in the year just entered upon to disperse the clouds of depression. The West Australian Government are evidently becoming daily more alive to the opportunities before them, and to the welfare of the hundreds of individuals who are flocking to their territory from the remotest corners of Australia. Their past inaction, however, is to be regretted. How much more would the comfort of those journeylog over the tracks from Southern Cross have been secured, to say nothing of the wider advantages to be bestowed, if a temporary telegraph line had been erected to Coolgardie, and if greater expedition had been displayed in the laying of a light railway line into the back country. The difficulties in neither case are unsurmountable, and any extra cost incurred would have been more than compensated for in the increase to the public revenue.

Another matter requiring urgent attention is the water supply and sanitation of Coolgardie. No doubt the aridity of the place has been magnified and overestimated. A country so well timbered as that appears to be must have a greater rainfall than is represented, and in the opinion of men who have visited the field, a scheme of conservation is all that is required. We are told that the country is admirable for dam making, and, this being so, no time ought to be lost in providing a water supply for the gold field. The government evidently recognizes this. It has been decided to purchase steam scoops for the purpose of sinking the necessary tanks, and more lately we learn that Mr. Jobson, who had charge of the Stephen's creek water works at the Barrier, has been appointed to construct and supervise the scheme. Our special representative, who is now en route to Coolgardie, forwards this week an interview with Mr. Z. Lane, who has just returned. He says, practically, that Coolgardie, while it possesses natural advantages denied to Broken Hill, will never approach the silver wonder in magnitude.

As yet too little work has been done to disclose the potentialities of the place; and until the wet season sets in and development work is commenced, the "good shows" of Coolgardie may be counted on the fingers of one hand. Two things it is very evident are necessary to render mining a success—capital and machinery. The claims in which dollying stone is found are few; the claims which have battery stone constitute the bulk, and money and plant are necessary to turn them to advantage. It is the latter which are being so freely placed on the market, and unless the public safeguard their interests by demanding that money subscribed shall go into the mine, instead of into the pockets of promoters, they must prepare to be disappointed.

HARVARD UNIVERSITY proposes to locate an observatory station in Arizona. Such a station has been the plan of Professor Pickering for years, but he has never before had the necessary financial backing. Percival Lowell of Boston has just donated a large fund for this purpose, and Mr. Lowell will go as a member of the party. A. E. Douglass, assistant in the Cambridge Observatory, will leave before the other members of the expedition, in order to make experiments. William Pickering, who led the Harvard expedition into Peru, will manage this work. The station in Arizona will be for visual investigation, as the Harvard station in Arequipa, Peru, is for photographic purposes. This will give the Cambridge Observatory two of the best locations in the world. The great Bruce photographic telescope now being tested will be shipped to Peru. It will be the largest of its kind in use.

The Water Supplies in the Arid Regions.

Part II.

By J. W. Powell, Director of the U. S. Geological Survey.

The Sources of Water Supply.

The preliminary question of the duty of water having been examined, it is proposed to indicate the source of water supply for the regions of the United States where irrigation is practiced. The rainfall of the arid region is variable, ranging from 3 to more than 20 acre-inches per acre of surface. It is to be carefully noted that the rainfall is variable not only from district to district, but also from year to year and month to month, and that the yearly and seasonal variations are very great.

Peculiar Conditions.—There are large districts in the arid region where, in extreme cases, not a drop of rain falls for an entire year, while in other years the very same regions experience terrific storms, and utterly arid deserts are suddenly transformed by the creation of storm-water streams, and rivers roll as floods, creeks as torrents, and brooks as leaping waters. Scattered throughout the arid region are many mountains towering above the valleys and performing the beneficent function of condensing the waters from the heavens and gathering them into lakes as natural reservoirs for perennial streams. These mountain-gathered waters constitute the most important supply for the fertilization of the land. Throughout the arid region there are many comparatively large districts which have no perennial streams, and these districts increase in size from north to south until districts as large as any one of a number of the Eastern States are found within a single living stream. But all of these districts without permanent rivers and creeks have storm-water streams that are sometimes of great volume. Throughout the arid region streams rise in the mountains and flow into valleys so arid that the waters are all consumed by the thirsty soil and evaporate into the wind-vexed air. Sometimes the sands do not drink up all of these waters, and salt lakes are formed, from whose noxious surfaces the waters are discharged by evaporation.

Having determined the mean rainfall of the arid region with a reasonable degree of accuracy, we have next to determine what becomes of the rain.

"Runoff" and "Flyoff."—When it falls upon the earth a part of the water is gathered into streams and is carried away into sinks, lakes and the ocean; let us call all this stream water *runoff*. Another part is carried away by the air, and this air-borne portion is in part evaporated from the surface of the land and from the leaves of plants, while another part is delivered to the air by transpiration. All this air-gathered water is drifted away by the winds, and therefore let us call it *flyoff*. The rainfall, then, is divided between runoff and flyoff.

The Geological Surveys has been engaged for several years in an investigation designed to determine the relative proportions of flyoff and runoff, in order to properly account for the disposition of the rainfall made by nature. It is proposed to give the general results of this investigation.

Knowing the rainfall, we must then determine the runoff, and this is done by gauging the streams. All the streams have not been gauged, but many have been, and these have been selected as typical cases.

An Analysis of Runoff.—It has been found by observation that the runoff is variable in three ways: 1. It varies with the amount of rainfall. If the rainfall is greater the runoff is greater. 2. It also varies with the character of the rains. When the rains come in great storms a large proportion runs off. A gentle shower is found to be almost wholly evaporated. If a year's rainfall is concentrated into two or three great storms, it will largely go into the streams, but if distributed through many showers it will be returned to the air. 3. Again, topographic conditions greatly influence the runoff. In a region of steep hills, mountains and canyons, with many naked rocks, the runoff is very great; in a level district, where loose sands and soils prevail, the runoff is small. Thus the rainfall becomes runoff in an unequal degree by reason of the inequality of storms and also by reason of the inequality of topographic features.

In gauging the rivers of the United States, results have been reached as follows:

Where the rainfall is 40 inches the runoff will be 20 inches; one-half is runoff and one-half flyoff. Where the rainfall is less, the proportions are changed. With 30 inches of rainfall, 18 inches will go to the air and only 12 inches to the stream—two-fifths runoff and three-fifths flyoff. But the amount will be variable in different districts, because of topographic conditions. With 20 inches of rain the amount of runoff will be 5 inches—one-fourth runoff and three-fourths flyoff. But the proportion will vary by reason of topographic conditions. Where the rainfall is 10 inches the runoff is a little less than 1 inch—one-tenth runoff and nine-tenths flyoff, but variable by reason of

topographic features. As rainfall diminishes, topographic conditions have greater control. At ten inches and below, topography almost wholly controls the runoff. Where the rainfall is the same, the streams may be few and small or many and great. There are large tracts of country in Arizona, southern California and Nevada where 10 inches of rainfall never gives a permanent stream and rarely a storm stream. There are other districts of country where 10 inches of rainfall gives birth to many living waters. If the lands are comparatively level the sands drink all the water; if the lands are traversed by canyons carved by rivers that have their origin in the mountains, a labyrinth of lateral canyons is formed and the rainfall is promptly gathered into streams which roll into salt lakes or into the sea. The rain in the desert is gulped down by the sand; the rain in the canyon is gathered into a creek.

What Becomes of the Rainfall?—We must now get a clear understanding of what is meant by runoff. Most of the streams of the United States ultimately discharge into the ocean; all of the water thus carried to the sea is runoff. Some of the streams of the arid region empty into salt lakes; all the water thus discharged is runoff. A very large number of small perennial streams of the arid region are discharged into what are usually called sinks—that is, into small valleys, where their waters are evaporated; all this water is runoff. There is still a great multitude of small storm-water streams that live only a short time after a rain and whose waters are gathered into sand valleys and evaporated, or into perennial streams; all such waters are runoff. Much rainfall sinks into the soil; a part slowly evaporates and becomes flyoff, but another part issues again as springs, and spring water is here considered as runoff. Rivers, creeks, brooks, storm-water streams and springs constitute this available water which we call runoff.

The water supply for irrigation in the arid region must mainly come from the runoff where the rainfall is 20 inches or less, for, with some exceptions, it is the runoff water which is used in irrigation. Crops are not raised throughout the entire season, but during a period varying in different portions of the country, and with different crops, from 60 to 150 days. If the rainfall of the entire year would come during the growing season, with a fair distribution throughout the days, a large part of the arid lands could be cultivated without irrigation, but, in fact, the rainfall is unequally distributed throughout the year.

Inequalities of the Rainfall.—The inequalities of rainfall through the season are very great. Everywhere throughout the arid region it often occurs, now here and now there, that no rainfall comes during the growing season, so that it is necessary for the farmer to provide by irrigation water for the entire crop. He may have rainfall and he may not. If, therefore, his agricultural operations are to be successful from year to year, he must provide all the water necessary for the crop. The water which can be utilized for this purpose must come from the runoff, with exceptions hereafter to be mentioned.

We have given certain laws relating to runoff for definite amounts of rainfall of 40, 30, 20 and 10 inches. Now, it is proposed to apply these laws to the arid region by district of country, and to show the average runoff by such districts; and for this purpose we shall consider runoff in zones or regions where the runoff varies from 20 to 30 inches, from 10 to 20 inches and from 0 to 10 inches. Of course, these zones everywhere run into one another; definite lines of boundary are not made in nature, and only approximate lines of boundary can be laid down.

(To be Continued)

The Greatest Bullion Output.

The largest bullion shipment ever made from the Comstock in one lot was on the night of December 31, 1877. It included 133 bars from the Consolidated Virginia mine and 129 bars from the California. The aggregate weight of the bars was 32,818 pounds, valued at \$1,099,099.71, says the *Territorial Enterprise*.

The total combined yield of Consolidated Virginia and California mines in the year 1877 was \$32,658,869. The total bullion yield of the State in that year was \$51,580,290, according to the annual statement published by Wells, Fargo & Co.

The total combined yield of the Consolidated Virginia and California mines from the discovery of the vast ore body on the 1,400 level up to July, 1878, was \$100,011,285.

At the close of the year 1878 these two mines had paid out in dividends up to that date a total of \$76,731,000. Since the consolidation in January, 1886, of the two mines, under the title of the Consolidated California & Virginia, the total sum paid in dividends from the ore discovery in the north end of the mine in that year was about \$2,500,000 and the total amount paid in dividends from ore extracted from the ground now consolidated under that title was more than \$80,000,000. The total yield of that ground to date is not less than \$120,000,000.

The Kern County Mines.

Gus Routh, a prospector, recently went from Porterville, Tulare county, to the new Kern county mines, and he writes thus to the *Enterprise* regarding the district:

We arrived here January 21st. Our trip was uneventful with the exception of heavy rains and snow storms while crossing the mountains. We are located thirty miles north-east of Mojave, thirty-five miles east of Red Rock and twenty-six miles east of Goler.

The climate here is fine, about the same as Porterville; some colder nights; no rain or snow, and very little wind. The altitude is 3100 feet, the nature of the country volcanic—three or four extinct craters in a radius of ten miles.

Two of the mines are paying well, avering from three to fifteen dollars per day to the man. There are some forty or fifty men here, all sociable, jolly fellows, always ready to help their fellow man. That is characteristic of the miner.

Considering the time we have been here we are doing well and have bright prospects ahead of us. We have some good claims. A large portion of the land in this district is located, but claims can be bought at nominal figures. For the benefit of anyone wishing to come I would suggest that they come via Tehachapi to Camerson. At that point leave the railroad to the right. Six miles from Camerson you intersect with the old Borax road, one of the best in the State. It is sixteen miles from there to Red Rock, twenty-six to Goler and forty-three to the Summit. On starting bring provisions to last six weeks, as you may want to return, and money to buy a dry washer. They cost from \$30 to \$75. Nothing can be accomplished without one. And do not expect to find nuggets on top of the ground, or growing on bushes. You may expect to meet with many hardships, and will have use for a pick and shovel.

Hay is worth from 1½ to 2 cents per pound, barley \$1.50 per sack, and can be bought at Red Rock, Goler, Kane and Mosquito Springs—all along the line of travel. Six miles from Camerson, at the junction of the Borax road, there is plenty of good water; five miles from Red Rock station, plenty of water; Kane, spring water for stock; Mosquito Springs, good water; and four miles from us as good water as can be had anywhere. All it costs is to help yourself.

Our nearest postoffice is Koehn, twenty-six miles west, in the Goler district.

Roasting Tailings.

Pankey & Fine, operating the Easton mine at Virginia City, have adopted a new scheme by which they claim they will save the full assay value of their ore, says the *Butte Inter-Mountain*. Their method of working the ore is as follows:

1. The ore is crushed, passing through a 7x10 Blake breaker.
2. Through a 24x30 roll.
3. Through a five-foot Bryan mill, wet crushing, 20-mesh screens.
4. Concentration of entire product on Frue vanners.
5. Drying the tailings from the vanners.
6. Roasting the semi-dried tailings and introducing chloride gas to release the silver and gold from the sand.
7. Amalgamation of the roasted material in pans and settlers.

The result is two products, viz., bullion and concentrates.

The idea of roasting the tailings after separating the concentrates is quite the reverse of the process employed in chloridizing silver mills, which lose 50 per cent of the gold in roasting as a whole, 10 per cent in the settlers and another small loss in amalgamation.

Mr. Fine first directed his attention to the white sand (silica particles) in the tailings. A gravity test was made in Denver where it was found that the transparent white particles, apparently not containing the slightest trace of metal, yielded 12 ounces in silver and \$4 in gold. Here then appeared the leakage which accounted for the loss when worked by any known process, but which can be saved to the highest percentage yet attained by the new departure alluded to.

The greatest portion of the gold is in the concentrates, which from the Easton ore is shipped and will yield from five to eight ounces in gold. Compared with the assay value, from 50 to 60 per cent of the gold and from 30 to 37 per cent of the silver is saved on the concentrators.

The idea of using a 20-mesh screen—besides increasing the capacity of the crusher to 25 or 30 tons per day—is the fact that the particles will calcine to better advantage.

A machine shop and other necessary accessories, besides the roaster and dry floor on top of the dust fines of the roaster, will be the new features added to the Fine & Pankey mill on Granite creek.

The Deep Leads of California.

Prof. Arthur C. Lakes of Golden, Colo., in *Colliery Engineer*.

A "deep lead" lies deep below the surface, often covered by beds of lava, especially in California. These lava beds may be many in number, and hundreds of feet in thickness. The "deep lead" is an ancient river bed.

In the Sierra Nevada the gold is derived from metamorphic crystalline rocks of the range, partly from quartz veins in the slates, and partly from gold distributed in minute quantities all through the metamorphic rocks. The quartz veins lie between the planes of stratification of the slates, also in irregular bunches and lenticular masses of limited extent. In many localities, the rocks are penetrated in every direction by little irregular quartz veinlets, which often carry gold, and in spots are extremely rich, even where the quartz vein is only an inch thick. In some California districts wherever a basalt capping exists, the drift beneath it is auriferous.

In California the modes of occurrence of auriferous gravel deposits are various.

Sometimes they exist in well-defined ancient river-beds under a capping of basalt which has filled the channels of the rivers in past ages. Again they appear in isolated mounds or hillocks evidently the remains of such channels, which being unprotected by a covering of lava, have been broken up by the action of the elements. Also in basins or flats, which have received the wash of these disintegrating rivers, also in low, rolling hills near the base of the Sierras and beyond the reach of the lava-flows. One of the most remarkable and important gold leads is that beneath Table Mountain in Tuolumne county. The waters percolating through these lava flows and reaching the gravels beneath are charged with alkali from the lava. These alkaline waters are charged with silica in solution from the same source. Hence the fossil drift-wood of these ancient rivers has all been silicified by these silicious waters. The gravels are also cemented by the same material. These percolating waters also contained iron, for iron pyrites is found in contact with the silicified woods. In this iron-cement, gold is found in rounded grains and in minute crystals, and threads deposited by a solution of sulphate of iron at the moment of the reduction of the latter to a sulphide.

The dead rivers of California are on the west slopes of the Sierra Nevada, from 500 to 7000 feet above sea level. The largest and richest lead is the big "Blue lead" traced 65 miles and even 110 miles. It was parallel with the main divide of the Sierra Nevada. The live modern rivers run at right angles to it, cutting canyons 1500 to 3000 feet deep. The "Blue lead" runs across these ridges from 200 to 1000 feet below their summit. The lead was discovered by following up surface washings. Miners found that the modern streams were richly gold bearing up to a certain point, increasing as this point was neared but ceasing when it was passed. These parts were in the line of the different streams and by following up indications the lead was eventually struck on several sections and tunneled on. The deposit is 300 feet deep composed of gravel boulders, clay and sand, so strata distinguished by degrees of fineness, by the character of the rocks, and the amount of gold, also by colors, the prevailing color being a blue-gray. Gold is coarser near the bottom, and contains a greater alloy of silver. The silver in the gold in the upper strata has been eaten out by sulphurous acid resulting from decomposition of iron pyrites. The whole deposit is like that in existing rivers, showing banks, bars, eddies, falls, rapids, and riffles. There is much gold in the eddies and but little in the rapids. The space between the boulders is filled with sand and contains gold, the bedrock is slate.

Where dead rivers meet, the "wash" is generally rich. Where a lead becomes very narrow, dips fast, and is inclosed between steep walls, the gold will be very sparingly distributed in holes and behind ridges and will be coarse in size.

Very large and abundant boulders in gold-bearing stream-beds are often a serious obstacle in getting out the gold, from the difficulty of handling them. More than one placer has been abandoned from this cause alone.

Willows Used to Build Dams.

The willows which grow along the shores of the Mississippi river are of no use in the arts, but when it comes to building a dam the engineers find nothing half as well as the humble willow. It lines the shores, and can be easily reached from the barges whereon it is transported, and it is so soft that it is easily cut and handled. It is woven into a great, loog, continuous mat.

One end of this is anchored to the shore, says the *Waverley*, on one side of the chute that is to be dammed, and the process of weaving is thence carried on straight across the stretch of water on a peculiarly shaped boat called a grasshopper. As fast as the mat is woven on grasshopper it slides into the water at the lower end of the

inclined weaving rack, and it is laden with rocks and carried straight to the bottom, and this is continued until the opposite shore is reached.

The mat is then covered to the proper depth, 12 to 15 inches, with rock, and then another mat, made in the same way, is woven and laid down on top of the first, and similarly weighted down, and this work is continued until the dam has risen as high as it is intended to stand, the finishing being always a heavy coating of rock that covers the willow and all.

The willow, always covered with water and the mud that inevitably lodges among the rocks of the dam, is kept sealed air-tight, and of course does not decay. It binds the rocks together and prevents the dam being shoved out of place by ice, or disturbed by the pressure of the current at high water. It is good for no other purpose save to hold a shore that is washing away with its roots, and for dam construction it is superlatively the thing.

Up the Klamath River.

Correspondence Blue Lake Advocate.

In my last letter I stopped writing at the Mettah mine. From here, if we go up the river four miles, we come to the old Morek Indian village, situated on the north side of the river at the foot of what is known as Morek hill. From here up the hill, something over a mile, brings us to the Morek hill mine, which is located 2300 feet above sea level. Here we come to a formation which seems to antedate any of the beds of gravel which we have examined. We have found the beds of gravel below this point to be of recent formation; in other words, they appear to have been formed by the present river system, yet we claimed they were fed by the Morek hill channel and not by the present river.

Then we claim for Morek hill another and entirely different formation, dating back to remote ages, to a time anterior to the present facial formation of the country, to a time before the present water courses had commenced to cut the channel, which to-day have reached a depth of thousands of feet below the gravel deposits in Morek hill. I will give two reasons for this conclusion, and then I will tell you something of the prospects and expectations of this mine, when properly developed and systematically worked.

Geological Formation.—1st. Taking the general trend of the lower Klamath we see the flow of water to be toward the northwest, while the Morek hill channel, as far as opened and traced, has evidently flowed toward the southeast. The present opening of the mine has every indication of being close to where this ancient channel was cut by the present river channel.

2d. The character of the gold, the sand and the gravel found in this channel is entirely different from anything found above this point on this river, while on the other hand the character of the gold and sand in this mine is exactly the same as in the mines we examined farther down the river, with the exception of Mettah, which was heavy gold. But Mettah was worked entirely by drifting, the gold all coming from the bedrock. The overflow of the gravel and the placing of it in those lower beds by the action of water have caused marked changes in the appearance of the gravel as compared with that found in Morek hill. But the close observer finds nothing in the gravel beds down the river that is not found in Morek hill; yet in the Morek channel we find some things which are not noticeable in the channels of more recent formation, as witness the immense quantity of decomposed gravel found in Morek. While in the beds below the decayed gravel has been dissolved and carried away, the solid went to fill up the beds of more recent date.

Morek Hill.—Now I will tell you something of the prospect in Morek hill, which, if I am rightly informed, would seem to leave no doubt in the mind of any one as to the richness of this mine. The present company have been to considerable expense in bringing the water to the mine.

One year ago they commenced opening the mine. At first the prospect was discouraging. On opening the channel they ran back 100 feet, at which point the gravel was 100 feet thick, and there did not appear to be enough free gold in it to pay for working, although a more thorough test showed fair prospects of rusty or gold-stained gravel, with base metals. The bedrock appeared to have nothing on the dip going into the channel, and it was found at this point that the rock had dipped so much that the works were not enough to drain the mine. After running back into the channel 150 feet, there was a stratum of gravel struck at the surface, 100 feet above the bedrock, which dipped as it went back at an angle of 50 degrees.

After going back 50 feet farther with dip of this pay stratum and the rise of the surface, there was a bed of gravel exposed 60 to 70 feet thick, from which it was impossible to take a pan of dirt and not find gold in it. Generally there would hundreds of colors show in a pan of dirt. But the gold was hard to save on account of the

light and float quality and the large quantity of heavy sand. The only wonder is that the company would hesitate with such a prospect as they have to put the water on and fit up the mine.

The Alaska-Treadwell Mine.

Correspondence of Dr. J. M. Buckley in *Christian Advocate*.

Douglas island is twenty-five miles long, and from five to eight in width. Twelve years ago it was an untouched wilderness. A few miners having made a camp on the shore, John Treadwell of San Francisco, a builder, took the claim of two of them to secure him for a loan of \$150. The debt was not paid, and he took possession of the property, afterward purchasing the claim of M. Pierre Joseph Ernsara, known as French Pete, for \$300. He associated with himself as equal partners Frye, Freeborn and Hill of San Francisco; and John P. Jones, now, as then, Senator from Nevada. Since that time they have spent over \$800,000 upon the works. It cost \$100,000 to complete a ditch eighteen miles long. They invested \$300,000 in experimenting to find the best process of chlorination.

As this word explains the whole process, I will define it. Gold, as is well known, is found in quartz; also in pyrites. In metallurgical operations there is often a residuum in which gold is found. It has been discovered that chlorine gas has the power to transform metallurgical gold into a chloride. When this is done it is a simple thing to dissolve the gold out of water and reprecipitate it in a metallic form. Platner, of Germany, invented the first of these operations about 1851; but his processes have been improved upon. The mill never stops, day nor night, summer nor winter, except to set new machinery. I went up to the open pits where the ore is quarried; saw the tremendous boring machinery above and the workmen breaking up the stone below. There are chutes to cars in the tunnels below, and gravity takes the ore down through the successive processes. Trains are always moving there; blasts are constantly being fired in the pits. Each day they mill 600 tons of ore, to do which costs \$1.25 cents per ton, and it averages from \$3 to \$7 per ton in value. This mineral region has never been examined by the Geological Survey, and it is a riddle to geology. Vegetation for a mile along the edge of the island is killed by the smoke from the chlorination works.

It is impossible to imagine the noise of the 240 stamps. The human voice cannot be heard, and for hours after going out of the mine there is an echo of the roar in the head. The stamps, like so many trip hammers, rise and fall and pound the ore fine so that it can be further treated.

The company has refused \$16,000,000 for the mine, and the gold actually in sight is estimated at \$28,000,000.

Direct Treatment of Pulp by Cyanide.

A modified method for securing direct treatment of the pulp leaving the battery is to be tried in connection with the cyanide process by the Robinson Company at Witwatersrand. Where pulp has been run direct into cyanide vats, two difficulties have been generally encountered, one being due to the packing of the sands as a consequence of currents in the solutions from which they are mechanically deposited, and the other to a segregation of the "slimes," or finer particles of the pulp, giving rise to imperfect filtration and extraction. These difficulties have, to a certain extent, been overcome by the use of hydraulic separators at some of the mines, but the principle of the method which will now be tried at the Robinson Company is to allow the pulp to settle through solutions which, below their surfaces, are in a state of rest, it being found that, by this means, successive portions of the sands carry down with them a certain proportion of the slimes; that an intimate mixture, without segregation, is thereby brought about, and that, in consequence, the resulting product is easily susceptible of cyanide treatment.

With this object, the pulp leaving the battery is run direct into intermediate vats fitted with bottom discharge, in which the mixing is effected, prior to the tailings being carried to the cyanide vats proper for treatment. It is asserted that the extra cost due to the necessity for a single handling is extremely small, and that the slight economic disadvantage thereby occasioned is amply counterbalanced by the increased percentage of extraction that can be secured, as a consequence of the tailings having been brought into the condition most suitable for chemical treatment, the mixing of the "slimes" and sand effected in the vats being naturally assisted by the discharge and re-delivery from trucks. To ensure a distribution of the pulp in a uniform manner without violence over the whole surface of the intermediate vats, an arrangement resembling in principle a garden sprinkler will be made use of. The cost of the extra vats required for this intermediate settling process will not be large, as the moment a vat is full it can be at once discharged.

Scientific Progress.

Air Reduced to a Solid by Cold.

About a year ago Professor James Dewar of London converted air and its constituent gases, oxygen and nitrogen, into liquids by means of intense cold, says the *New York Tribune*. The temperatures necessary were 182 degrees below zero, C., for nitrogen; 192 below for oxygen, and about 200 below for air. Soon afterward, although it did not attract much attention then, he actually congealed air. In some public lectures given in London, a few weeks ago, he again produced solid air, at a temperature of 210 below zero, C., or 346 below, Fahr. This time the feat created a public sensation, and the non-scientific press is now making the matter generally known, although Professor Dewar has, in the meantime, done little but improve his apparatus so as to increase its output. He has not produced any more intense cold than before.

So small was the quantity of solid air made on this recent occasion that it could not be passed around for inspection conveniently. The demonstration of what he had done was made to the audience by means of a ray of light thrown by a lantern through the freezing tube upon a screen, and what was shown to be a liquid at one time afterward appeared in such a condition that it would not move when shaken.

These low temperatures, toward which the chemists have been striving for years, are to be regarded only to a limited extent as ends, and more as means to ends. To be sure, it would be a great thing to reach 273 below zero, C. (459 Fahr.), for this is the absolute zero below which it has been supposed impossible to go. And it was inaccurately reported last summer that a Frenchman, Pictet, had actually reached that goal. But the important practical phase of all this business is the change wrought in the properties of matter by such temperatures. Among the new points brought out this winter by Professor Dewar are that at 180 degrees below zero, C. (292 below, Fahr.), metals gain in tensile strength, steel becoming almost twice as strong as at ordinary temperatures; colors are somewhat modified, and rubber becomes more extensible. An electrical discharge, moreover, which usually goes through a vacuum with a beautiful luminosity was literally frozen out and driven back when the vacuum tube was reduced to a very low temperature.

The means employed in producing this cold, it will be remembered, is the evaporation of highly volatile substances. If, in a room where the air has a temperature of 70 degrees Fahr., one pours a few drops of water on the mnsln covering of a "wet bulb" thermometer, the mercury will fall 10 or 12 degrees, possibly more, the result depending on the atmospheric humidity. But if, instead of water, alcohol is used, its greater evaporative power will lower the reading about 25 degrees, and good sulphuric ether about 50. Thus one can, with proper appliances, freeze water in a warm parlor. But there are much more volatile substances than these; namely, gases which have been reduced to liquids under enormous mechanical pressure, and then liberated. Sulphurons (not sulphuric) acid may be used to freeze mercury; chloride of methyl gives 70 or more below zero, C.; carbonic acid, 100 below; and bisulphide of carbon and nitrous acid, 140 below, C., or 220 below, Fahr. To liquefy oxygen, Professor Dewar employed three steps: First, he put the gas under great pressure, about 750 pounds to the square inch; this enabled him to secure the result at 145 below, instead of 192 below. Then he liberated nitrous oxide gas, which had been under a pressure of 1400 pounds, by which process he was able to produce a temperature of minus 90 C. around a small chamber, into which he introduced ethylene under a pressure of 1800. When the inner

receptacle was full, evaporation was resorted to, and facilitated by a vacuum. This gave minus 145 degrees. Oxygen being thus liquefied and under pressure, it was employed in the same way as ethylene, freed from pressure and evaporated in a vacuum, and then the extreme temperatures already referred to were secured. There is enormous waste in handling these liquids. For every pint of oxygen in that form applied to use, Professor Dewar loses nine. This fact and the mechanism for compressing the gases make the work enormously expensive.

Inter-Relation of Forces.

Water freezes and becomes ice at 32° F., whereas mercury only freezes at 39° below zero F.; olive oil, on the contrary, shows signs of congelation at from 40° to 45° F. The three substances quoted being all liquids, the difference in the loss of heat requisite to bring them to solidification is very great indeed, says the *Westminster Review*.

The action of heat on fluids or solids is equally various. Water boils at 212° F.; lead melts at 612°; the fusing point of gold is 2016° and of iron 3000°. We give these particulars in order to show what enormous changes can be effected by cold in the transmutation of a substance from a liquid to a solid, or by heat from a solid to a liquid state. Ether boils at 96° F., but has never been frozen by the severest cold. The forces exerted by the action and reaction of heat and cold are best exemplified under the head of steam, which has only been called forth and made use of by man since about the middle of the eighteenth century, but it has been in action on a gigantic scale in nature for probably hundreds of thousands of years, it being the opinion of many geologists, including Lyell, that it is the generation of steam, whether developed by the internal heat of the earth in a state of fusion or whether by that of the chemical action of the elements in the bowels of the earth developing heat, which, acting on water and thus generating steam, is the great force that throws up such enormous rocks and masses of lava as Etna has lately been doing. The rocks and lava thus thrown up are in a state of fusion by heat; but they gradually cool by exposure to the air and form solid rocks and mountains. This action and reaction has been going on for thousands of years with little cessation.

Heat and cold, again, cause the oceanic currents on our earth between the equator and the poles, and *vice versa*, and thereby affect the earth's magnetism or polarity, not only on our globe, but probably all throughout the universe. This is borne out by the fact that the "aurora borealis" is decidedly an electrical phenomenon, which takes place in the highest regions of the atmosphere, since it is visible at the same time at places very distant from each other. Dr. Faraday conjectures that the electric equilibrium of the earth is restored by the aurora conveying the electricity from the poles to the equator."

The Stethophone.

One of the new telephones now made available to the public by the expiration of a recent patent combines in a single instrument the transmitter and receiver. While this is in use, one part is pressed against the ear and another, curving under the chin, rests lightly against the throat. A button here receives the vibrations of the speaker's larynx and transmits them to the electrical parts of the apparatus. It is not necessary to aim the voice into a tube or cavity. A person talks into the open air without reference to any box on the wall. One advantage claimed for this contrivance is that, as the button is in contact with the user's throat, no other sound in the same room can vibrate it when he is not speaking, and hence the listener is not liable to be confused as he

now is sometimes by strange voices and other loud noises. This instrument is called the "stethophone" from its partial resemblance to a stethoscope, which physicians use in detecting faint sounds in the heart and other human organs.

EASTERN PRICES BEATEN. San Francisco Pioneer Screen Works

JOHN W. QUICK, Proprietor.
IMPROVED FACILITIES, FINEST WORK, THE LOWEST PRICES.
Perforated Sheet Metals, Steel, Russian Iron, American Plainish, Zinc, Copper and Brass Screens for all uses.
MINING SCREENS A SPECIALTY.
221 & 223 First St., San Francisco.

QUARTZ SCREENS
A specialty. Round, slot or hurred slot holes. Genuine Russian Iron, Homogeneous Steel, Cast Steel or American plainish Iron.
Zinc, Copper or Brass Screens for all purposes. Cal. Ironia Perforating Screen Co., 145 & 147 Beale St., S. F.

UNION IRON WORKS, SACRAMENTO.....CALIFORNIA.

ROOT, NEILSON & CO. —MANUFACTURERS OF—

STEAM ENGINES, BOILERS
And all kinds of
MACHINERY FOR MINING PURPOSES.

FLOURING MILLS, SAW MILLS AND QUARTZ MILLS.
Machinery constructed, fitted up and repaired.

Front St., bet. N and O, Sacramento, Cal.

INVENTORS, TAKE NOTICE! L. PETERSON, MODEL MAKER,

Experimental machinery and all kinds of models. Tin and brasswork. All communications STRICTLY CONFIDENTIAL.

J. F. CROSETT,
628 Sacramento St., San Francisco, Cal.
Gold Mines Bought and Sold on Commission. Five first class meritorious mines now for sale at from \$25,000 to \$300,000. Correspondence solicited.

LIGHTNING WELLS
WELL MACHINERY Works.
All kinds of tools. Fortune for the driller by using our Adamantine process can take a core. Perfected Economical Artesian Pumping Rig to work by Steam, Air, etc. Let us help you. THE AMERICAN WELL WORKS, Aurora, Ill.; Chicago, Ill.; Dallas, Tex.

FRANCIS SMITH & CO., MANUFACTURERS OF

SHEET IRON & STEEL PIPE
FOR TOWN WATER WORKS.
Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.
NO. 180 BEALE STREET, SAN FRANCISCO, CAL.

Iron cut, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for making Pipe. Estimates given when required. Are prepared for coating all sizes of Pipes with a composition of Coal Tar and Asphaltum.

Adamantine Shoes and Dies

—AND— CHROME CAST STEEL

Cams, Tappets, Bosses, Roll Shells and Crusher Plates.

THESE CASTINGS ARE EXTENSIVELY USED IN ALL THE MINING STATES and Territories of North and South America. Guaranteed to prove better and cheaper than any others. Orders solicited subject to above conditions. When ordering send sketch with exact dimensions. Send for Illustrated Circular.

Manufactured by CHROME STEEL WORKS, Brooklyn, N. Y.
H. D. MORRIS, Agent, 220 Fremont St., San Francisco.
Special attention given to the purchase of Mine and Mill supplies.

Mechanical Progress.

A New Method of Exchanging Messages Between Ships.

A new method of signaling through water is the invention of Captain Neale, and is intended for the exchange of messages and the carrying on of conversation between ships on the sea or on rivers, whether moving or stationary, or between ships and light-houses and harbors, forts or piers on the shore, says the *World's Progress*. Communication is effected without any connection whatever between the two objects except the body of water in which the ships float or the lighthouse stands. The system utilizes a well-known law of acoustics. If a musical note in a given key be sounded, an object capable of emitting sound in the same key will, under certain conditions, sympathetically respond with a sound similar to that which induced it, it being, of course, a primary condition that the two objects shall be normally tuned in unison. Capt. Neale's invention is based on this principle, and, utilizing the high conductivity of water for the transmission of sound, he has constructed a signaling apparatus consisting of a transmitting and receiving instrument, which are effectively operated without being in any way connected with each other, except through the medium of water.

In the recent test the apparatus was mounted on two punts, moored about two-thirds of a mile apart, and carried a transmitter and a receiver respectively. The transmitter consists of a bell about 16 inches in diameter, attached to the lower end of a framing, which is fixed to the side of the punt, at the upper end of which is a crank handle. This handle, worked from the punt, actuates a double heat hammer, which strikes and sounds a bell submerged about six feet. The Morse code is employed. The receiving apparatus consists of a pair of metallic drums about ten inches in diameter, open at one end and fixed, mouth to mouth, upon a piece of board placed between them. These drums, suspended in the water, are connected up with a small battery, and through it with a tape-recording instrument. Messages were correctly transmitted and recorded. The speed of operating was somewhat slow, as the signaling had to be carried on by hand instead of by electricity, which will shortly be utilized. The trial, however, was most successful, and is said to have demonstrated the practical character of the invention and the correctness of the principles upon which it is based.

An Ingenious Smoke Consumer.

The "air grate" is a device, by means of which, it is claimed, as nearly as possible complete combustion is obtained, all the carbon in coal extracted, and the combustible properties of other fuels more fully utilized than heretofore, says the *Coal Trade Journal*. The grate is constructed of hollow cast-iron bars, so made that a regular pressure of air can be supplied into them, coming out through a slot on the top of the bar, and at that point causing rapid and perfect combustion with the aid of the natural draft.

This method of supplying air does not constitute a forced draft as commonly understood, because the natural draft is also used in conjunction with the air blast admitted through the bars, the combination of the two, that is, the natural draft and the air blast, producing perfect combustion. It will be seen that this system renders the use of fine coal and screenings possible, because the oxygen is carried to every part of the mass of coal and consumes all the carbon that is in it.

It has been demonstrated in actual practice that the use of this system of hollow grate bars, patented by C. H. Gadey of Chicago, effects a saving of 25 to 30 per cent in the cost of fuel. In cases where boilers are

not making the required amount of steam it increases their capacity 25 to 30 per cent. The difference in temperature between the grates and coal, caused by the circulation of air through the bars, prevents the adhering of clinker, and in addition to this makes it impossible for the bars to burn out. Thus, their extreme durability becomes an important point in considering the cost of this system. These grates will replace any other kind of grate bars without involving any change whatever in the construction or form of the fire box or chimney.

A New English Torpedo Boat.

The English Navy is being augmented by the addition of a number of new torpedo boats, or, more technically, torpedo-catchers, some 42 in all, costing in the neighborhood of \$200,000 each.

The Havock, the latest acquisition, built by Messrs. Yarrow, has developed a remarkable speed. She is propelled by twin screws of the three-blade pattern. These screws are actuated by engines of eighteen inches stroke. The cylinders are 18, 26 and 39½ inches. Power is furnished the engines by two locomotive boilers provided with copper fire-boxes and copper tubes. The total grate surface is about 100 square feet, and the total heating surface about 5000 square feet. The dead-weight on board was 35 tons. In a trial for speed, the Havock made a three-hours run in rough weather with a 30-mile wind, at 26 knots per hour. On the measured mile, the mean of four runs was 26.78 knots, the fastest mile being made at the rate 27.56 knots and the mean of the next two runs was over 27 knots. The indicated horse power was 3400, and the engine revolutions 362 per minute. The Havock is equipped with the usual hood or turtle back, although some modifications have been adopted to insure a drier deck when the craft is heaving a heavy sea.

In the trial of the Havock at an economical speed, in an endeavor to learn what distance the vessel would steam with the fuel on board, she made 11.2 knots with less than a quarter ton of coal consumed per hour. At ten knots, three and one-half hundredweight per hour sufficed. As the hulkers are of 60 tons capacity, the Havock can make 3500 knots at one coaling.

Useful Information.

The Name of California.

Thomas E. Slevin, LL. D., recently delivered an unusually interesting lecture on the "Origin of the Name California" before the Geographical Society of the Pacific at Union-square Hall. Mr. Slevin first proceeded to explain the various alleged origins of the word California. These he divided into three classes, the most plausible of which was the supposition that the name was derived from a misunderstanding of some words used by the natives when first addressed by Cortez or one of his followers. This was satisfactorily explained away and the speaker then told in a pleasant manner what he conceived to be the only legitimate conclusion to be drawn from the various explanations of the origin of our State's name.

The word California was first used in a work on Spanish chivalry published in 1510. This work was an alleged history of the adventures of "Amadis of Gaul and his son Esplandian." It was of great length and divided into a large number of short stories, one of which was the manner in which "Califa, the Queen of the island of California, a country inhabited only by women, who lived as Amazons and had gold without end," saved Constantinople from an attack by the Persians. This story, as well as others, was widely read by the people of Spain, and by many regarded as fact. Among the staunch believers were the members of the Cortez expedition,

who, upon landing upon the peninsula of Lower California, imagined they were on an island which, owing to its apparent riches, they named after the fable isle, and Cortez himself called the new country "California."

Secret of His Health.

Many hold to the opinion that the majority of people eat too much. We hardly think, however, that people engage in the ordinary avocations of life will be willing to adopt the regimen of a famous old man as told in the *New York Sun*:

He is far along in the seventies, is an indefatigable worker, free from deafness, eyeglasses, rheumatism and other indications of advancing age. His name is withheld at his own request but his method of life is of interest. Until he was forty years of age he suffered from a number of pretty ills. Indigestion was one of them and an overburdening amount of fat another. Almost incessant headaches at night rendered his work uphill and difficult. It was not until he had passed his fortieth year that he came to the conclusion that nearly all his ills came from excessive eating.

He put himself at once upon a regimen which he has maintained for upwards of thirty years. Like Capri, Napoleon and many other great men, he rises at six in the morning in winter, and at five in the summer, and takes a light exercise before dressing. Then he lights an alcohol lamp, boils some water and makes a cup of coffee of two parts of Java and one part of Mocha. The coffee is selected with great care. After it has boiled for fifteen minutes he pours a little cold water on it to settle the grounds, puts in some milk, drinks two cups and eats three or four biscuits. Then he goes in his study and undertakes the most serious problem of the day. For six hours he works steadily. His mind has not been disturbed by any incident, not even by the entrance of the servant with his breakfast. At one o'clock he eats whatever his appetite craves. There is no restriction whatever at this meal. After this he walks religiously for an hour, and during that day not another mouthful of food passes his lips. If at eight or nine o'clock at night a feeling of hunger comes on he takes a glass of milk, but nothing more. He has come to the conclusion that excessive eating kills more people than excessive drinking.

Crossing the Limbs When Sitting.

It really seems as if the women could not be allowed to do anything without being told it is injurious. Yet it is well to heed such suggestions as the following, which is doubtless true. Women who sit with their legs crossed, to sew or read, or to hold the baby, are not aware that they are inviting serious physical ailments; but it is true, nevertheless. When a man crosses his legs he places the ankle of one limb across the knee of the other, and rests it lightly there. A woman, more modest and restricted in her movements, rests the entire weight of one limb on the upper part of the other, and this pressure upon the sensitive nerves and cords, if indulged in for continued lengths of time, as is often done by ladies who sew or embroider, will produce disease. Sciatica, neuralgia, and other serious troubles, frequently result from this simple cause. The muscles and nerves in the upper portion of a woman's legs are extremely sensitive, and much of her physical structure can become deranged if they are overtaken in the manner referred to.

Lemon Juice for Gout.

Details for this remedy were published in the *Lancet*, and the superiority of the remedy over every other demonstrated; yet, strange to say, it has since fallen into comparative desuetude, probably from its very simplicity. It is a fact not generally known that no object in nature contains a larger amount of potassa than lemon juice, though popularly supposed to be acid. This is only

because it is naturally joined to a sharp acid, citric, but which has such feeble affinity for the base that it readily parts with it in the body, and leaves the free potassa to unite with the lithic or uric acid in the system. One case was that of a licensed victualer, a free-liver, who for years had been a martyr to gout. His joints were enormously enlarged, and several of them covered with chalky stones. He was given lime juice largely. The good effects were perceptible within 24 hours after the first dose, and in less than a fortnight a complete cure was effected. The swollen joints gradually resumed their usual size and mobility, the chalky deposit returned to the liquid form and was absorbed. The remedy was continued for several weeks, and it became the favorite drink of the patient. In two years his hands were as small and symmetrical as if they had never been disfigured, and he continued in perfect health.—The Leisure Hour.

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE
AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND
CHEMICAL APPARATUS.

45 & 65 First St., cor. Mission, San Francisco

We would call the attention of
Assayers, Chemists, Mining Com-
panies, Milling Companies, Pros-
pectors, etc., to our full stock of
Balances, Furnaces, Muffles, Crucibles, Scor-
ifiers, etc., including, also, a full stock of
Chemicals.

Having been engaged in furnishing the
supplies since the first discovery of mines in the
Pacific Coast, we feel confident from our experi-
ence we can well suit the demand for these
goods, both as to quality and price.

Agents of the Devoe Fire Clay Co., and
for the Morgan Crucible Co., Battersea,
England. Also for E. G. Deoalston's Silver
Plated Amalgam Plates. The plates of this well-known
manufacturer are thoroughly reliable, and full weight
of silver guaranteed. Orders taken at his lowest prices.
Our Illustrated Catalogue and Assay Tables sent free
on application.

JOHN TAYLOR & CO.

Dewey & Co.'s Scientific Press
Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY
presents many and important advantages as a
Home Agency over all others, by reason of long
establishment, great experience, thorough sys-
tem, intimate acquaintance with the subjects of
inventions in our own community, and our
most extensive law and reference library, con-
taining official American and foreign reports,
files of scientific and mechanical publications,
etc. All worthy inventions patented through
our Agency will have the benefit of an illustra-
tion or a description in the MINING AND SCIENTIFIC
PRESS. We transact every branch of
Patent business, and obtain Patents in all coun-
tries which grant protection to inventors. The
large majority of U. S. and Foreign Patents
issued to inventors on the Pacific Coast have
been obtained through our Agency. We can
give the best and most reliable advice as to the
patentability of new inventions. Our prices
are as low as any first-class agencies in the
Eastern States, while our advantages for Pacific
Coast inventors are far superior. Advice and
Ordnances free.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved
Concentrating Belt manufactured in San
Francisco. We keep always on hand
Belts suitable for the Triumph and Frue
machines, but can make any length or
width desired. The advantages of these belts over
any others will be readily seen by practical millmen.
First, the flanges or edges of our belt stand at an acute
angle inclining toward the center, and therefore readily
conform to the change of direction while passing over
the end rollers; thus the vibration and loss caused by the
frequent breaking of the flanges of the old style belt is
practically done away with. Again, our belts, at intervals
of two to four feet, have a very slight rifled surface for
the space of three inches, which tends to equalize the pulp
on the belt, and prevents it from banking on the sides and
forming channels through the center. These slight rifles
also save very fine sulphurets and the quicksilver that
would otherwise escape with the tailings from a belt,
the surface of which is entirely smooth. We can safely
say that it is a better concentrator belt than has ever
been manufactured. It will last much longer and
will handle more pulp. We also manufacture smooth belts with same flanges when desired.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist
who has devoted many years to assaying and working pre-
cious ores on the Pacific side of the American Continent.
He writes whereof he knows from personal practice, and in
such plain and comprehensive terms that neither the scientist
nor the practical miner can mistake his meaning.
The work, like Mr. Aaron's former publications ("Testing
and Working Silver Ores," "Leaching Gold and Silver
Ores") that have been "successfully popular" is written in a
condensed form, which renders his information more readily
available than that of more wordy and less conscientious
writers. The want of such a work has long been felt.
It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Ma-
terials; The Assay Office; Preparation of the Ore; Weighing
the Charge; Mixing and Charging; Assay Litharge; Systems
of the Crucible Assay; Preliminary Assay; Dressing the
Crucible Assays; Examples of Dressing; The Melting in
Crucibles; Scorification; Cupellation; Weighing the Bead;
Furnishing; Calculating the Assay; Assay of Ore Containing
Quartz Metal; Assay of Roasted Ore for Solubility; To
Assay a Oupel; Assay by Amalgamation; To Find the Value
of a Specimen; Tests for Ores; A Few Special Minerals;
Solubility of Metals; Substitutes and Expedients; Assay
Tables.

The volume embraces 130 12mo. pages, with illustrations,
well bound in cloth; 1889. Price, \$1, postpaid. Sold by
DEWEY PUBLISHING CO., Publishers, No. 220 Market
Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead,
Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and is
separate from Part I, and treats of Gold and Silver Bullion;
Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion;
Assaying Bullion; Humid Assay of Silver; Gay Lussac's
Method; Volhart's Method; Manipulation; Lead Ores; Cop-
per Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and
Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur;
Salt; Note.

One of the methods given for the Assay of Copper is new
original and exact, as is also one of the processes for Zinc.
The book contains 161 pages with illustrations, and is
strongly bound in cloth. Much of the original text is re-
placed by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING
CO., Publishers No. 220 Market St., San Francisco.

THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS Was awarded the Highest (Bronze Medal) Premium at Mechanics' Institute, 1890 and 1891. MORE THAN DOUBLE THIS CAPACITY with one-half less power and occupying less than one-half the space of any other concentrator. Built of Best Steel and Wrought Iron. Strong and Durable. Price \$575 f.o.b. Send for Catalogue and Testimonials. The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge. THE IMPROVED MACHINE HAS THE FOLLOWING MERITS: First—The improved belts, which consist of seven, are constructed and arranged so as to allow each belt to receive a portion of the pulp in such a manner as to relieve the machine of its load, thereby giving it twice the capacity of other concentrators, and enabling it to work from 12 to 15 tons of ore per day. Second—The machine equalizes the load by having several compartments, thereby working more regularly and with much less attention than is necessary to give other concentrators using wide belts. Each of the belts on this machine takes care of the pulp that is allotted to it—in this way preventing the pulp from running to the lower side of it, as is the case when a machine becomes out of level where wide belts are used. Third—The belts run on a perfect line, needing no adjustment to prevent their running from side to side, as in other concentrators. Fourth—The belt surfaces are improved by indentations and corrugations, causing the Concentrator to save fine sulphurets and quicksilver, and perform close work. Fifth—The belts have fluted or corrugated edges, to form an expanded top edge, which effectually prevents from cracking. Sixth—The feed arrangement is perfect. Seventh—The machine is constructed of iron, with steel crank-shaft self-oiling boxes, and everything made in the most thorough manner, enabling it to run with very little attention or wear.

GEO. E. WOODBURY, Manufacturer, 213 to 219 First Street, San Francisco, Cal.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

THE '54 MINE.—Record: M. D. Nixon, Dr. Nichols and Will Templeton paid a visit to the '54 mine this week. Everything is in fine working order there, and six men are employed. The monitor is running night and day against a 20-foot bank and the earth is disappearing at a lively rate. The company has expended about \$3000 in getting things in shape for work, but they undoubtedly have a fine property and will reap big returns for their outlay.

LAIN OFF.—Dispatch: Quits a number of the miners at the Zells mine have been temporarily laid off during the past few days, owing to the large amount of surface water coming into the mine. It requires the entire time of the engineers to keep the water down, and even then they are making but little gain on the inflow. This misfortune, however, will soon be overcome if the present fair weather holds on a few days longer.

Calaveras.

WORK DISCONTINUED.—Echo: Operations on the Gold Hill mine at Smith's Flat have been discontinued for the present. It is also reported that work on the Smyth mine, near Angels, has been discontinued.

TO REOPEN.—Among the mines in this section which it is rumored will reopen this spring, says an Angels correspondent, are the Smith, owned by Demarest of Altaville; Smith, by Lindsay, Prince & Co.; Stickle and Bennett, by Lindsay & Prince; Gold Cliff, by Hayward, Lane & Co.; Tullock, by Hayward & Co.; Eastland, by Eastland & Co., of San Francisco; Colman, by James V. Coleman; Fritz, by Fritz & Co.; Gold Hill, by Eastern capitalists. There are also the Fitch, Altaville, Keystone, Curtiss, Eclipse and other mines that have had prominence.

UNDER HIS STABLE.—B. R. Prince, the well-known pioneer of Altaville, above Angels, Calaveras county, says that under his stable is good paying ore, and probably in the near future the ground will be developed and a rich strike made at about 14 feet. Mr. Prince's other mines, the Cherokee and Knob Hill, have some rich rock.

El Dorado.

SIX DAYS' RUN.—Nine stamps of the mill at the Gregory mine, El Dorado, after a six days' run, produced last Monday a bar of gold about eight inches long, two inches wide and an inch thick, worth about \$3000.

Inyo.

THE ALABAMA DISTRICT.—Index: The old Alabama district is attracting some attention these days. A claim of 20 acres, over 4000 feet in length by 200 wide, was located last week.

Aids from the rich seams of gold quartz, the placer belt is the most interesting, from the fact that it is most exposed of what appears to be a vast post-pliocene river extending along the base of the west wall of the Sierras from Bodie to Redrock.

In the "Kearsarge and Alabama" days of 1865-66 much gold was taken out of both, but more especially the latter district. The best mines of Kearsarge Peak are under patent to owners who won't work them. As neither are more than a dozen miles from town, they are too near home to be appreciated.

Kern.

BOUGHT A GROUP OF MINES.—Bakersfield Californian: O'Connor and Stenben of Visalia have just completed the purchase of the Stuts & McKee group of gold mines in Agua Caliente district. These mines have yielded over \$20,000 during the past few years and have only been worked about 60 feet from the surface. The three veins—the Wandawa, Bonita and Bell Ruffian—will now be extensively developed, and eventually increased milling facilities will be added. The present mill consists of arrastras run by steam power. During the past workings considerable base metal was found which was thrown on the dump as unfavorable to amalgamation. Assays show that this ore carries about \$40 in silver, at present prices, to the ton, and some of it as high as \$500 a ton in gold.

Nevada.

ANOTHER SALE.—Grass Valley Union: Joseph Southern, the well-known millman, has sold his quartz claim bearing his own name, together with 15 acres of patented ground and improvements thereon, consisting of a dwelling house and outbuildings, to James D. Hague. The price paid was \$3000. The southern claim adjoins the New York Hill and Rocky Bar mines on the south, which claims were purchased some time ago by Mr. Hague.

CAVED IN.—Union: The recent heavy storms caused the Original Hartley mine to cave in for a distance of 30 feet across between the old perpendicular and the new incline shaft. When the company gets ready to clean out the shaft it will have considerable work to do to remove the debris.

MORE STAMPS.—Herald: The Gold Flat mine is said to be turning out some splendid rock now, and the company is preparing to build a mill. They will put in five stamps at present, but will lay foundations for a ten-stamp mill, with the expectation of adding five stamps this year.

This is good news. More stamps means more money in circulation.

THE LEDGE STRUCK.—Grass Valley Telegraph: The ledge in the crescent at the Crown Point mine was struck several days ago. Some of

the ore from the mine was brought to town today and it was very heavy with mineral and sulphurets. This ledge was out at the depth of 200 feet and it measured fully three feet in thickness. This is on the new crescent being run by Messrs. Polkinghorn and party. The strike is regarded as very important.

Placer.

TO REPAIR A TUNNEL.—Colfax Sentinel: Men have been set to work in the old Larson tunnel near Alta to repair it. The Alta Mining Company will run a tunnel into their channel from this tunnel. It is expected that by continuing this tunnel it will strike about ten feet below the gravel in the channel. It will be several months before the tunnel will be completed. A day shift and night shift are at work, and the tunnel will be pushed ahead as rapidly as possible.

Major Hens of the Dabris Commission inspected the Polar Star dam at Dutch Flat last week and pronounced it satisfactory.

NEW MINING COMPANY.—Colfax Sentinel: The Alta Gold Mining Company has recently incorporated with the following directors: W. M. Hall, W. S. Miller, F. S. Chabonne, J. P. Edhoff and J. E. Doolittle. The company has been organized for the purpose of working the Alta mine at Alta in eastern Placer. This mine promised very well a few years ago, but owing to litigation and other hindrances it was closed down. The last gravel worked promised the best of all. The gravel is of the white lead of the same character as the gravel in the famous Hidden Treasure mine at Sonny South. There is every reason for believing that, with improved facilities for working, this mine will become a good paying property. The company has not yet decided as to the manner in which the mine is to be worked, but that will be decided very soon and work will be begun as soon as the weather permits. The company has organized with a capital stock of \$1,000,000, of which \$550,000 have already been subscribed.

Plumas.

THE PLUMAS IMPERIAL.—National Bulletin: Col. M. H. Day, president and manager of the Plumas Imperial Mining Co., accompanied by Supt. Thomas, went over to Greenville Monday, Feb. 12th, purchased 3000 feet of the large Dutch Hill pipe owned by General Chipman, and let a contract for taking up and hauling the same to Hungarian Hill, there to be used in conveying water from the ditch to the hydroelectric mine. In all, there will be about 4000 feet of pipe in use. The pressure secured will be about 480 feet, thus securing good execution. Work on the dam is progressing rapidly, and it is expected to be completed by the end of the present month. The atmosphere is 30 feet wide at the base and will be 10 feet wide at the crest. It will rest on a solid rock foundation, and will be perfectly secure. The site is most advantageously located, enabling the company, by a comparatively small expenditure, to secure a very large impounding reservoir, amply sufficient for the purposes desired. As soon as this dam is completed, the Plumas Imperial will begin the erection of another dam—one at the outlet of Dean's Valley, to enable the company to store and hold in reserve a large supply of water for mining purposes. This will be a most important improvement, adding much to the facilities for working the property owned by the corporation. All this work has been outlined and arranged for, and it is expected to begin mining by the first of May.

Riverside.

STRUCK GOLD.—Riverside Enterprise: It is reported that Messrs. Lang & Son, cattle men on New river, have struck rich gold property in the hills about 20 miles northwest of Indio station on the Southern Pacific Road, and seven miles west of Tingman's two-stamp mill. The ledge is three feet wide and crops for about 4500 feet. Samples taken from three different points give an average assay of \$500 in gold to the ton. The gold is very coarse in the quartz, single pieces worth 60 cents being found. Ten tons of the croppings were taken over to Tingman's mill and yielded \$7000. The finders have a large force of men at work.

San Bernardino.

NEW MILL.—The Morongo Gold Mining and Milling Company, in San Bernardino county, has purchased a ten-stamp mill, which is being moved to the mines, and it is expected to have the property on a producing and paying basis in the near future.

NEW MACHINERY.—Courier: The Miller quartz mill at Middle Creek is to be remodeled and new machinery added. The mill is well located and could be made a paying property working custom contract ore alone.

Sierra.

Forest Hill Ore.—Messenger: The Maple Grove Co. had to suspend operations for a week on account of the freezing weather. Their gold became frozen and could not be thawed (?) out. Jas. Pearson is still manager and bids fair to outlive an Oscar Jones or Blus Lead Joe in this science of gravel mining.

South Fork Ore. are still pushing their prospect tunnel ahead, and expect to open up the rich ground south of the Old Extension by spring.

The quartz prospects on Kanaka side are looking well and a genuine boom is expected for next summer. Chas. Hegarty, of Moore's Flat, Nevada county, has struck it rich in the Old Plumbago at Minusota, and is reported to be taking the "stuff" out by the bucketful. All the other mines in this vicinity are at a standstill on account of the weather.

Siskiyou.

CRUSHER GOOD ORE.—Journal, Feb. 21: Some 34 tons were crushed at the Siskiyou mine, on

Humburg creek, lately, which yielded \$12 a ton, with four or five tons of the same being waste rock. It was run through the steam mill at the claim by Frank Hegler, who used fine steel wire screening. The owner of the claim, Thos. Orr, is well pleased with the prospect obtained, and intends starting work again when the weather settles and the ground dries out a little. There is a large amount of the same kind of quartz in the claim, easy to take out, and it is believed still better pay can be realized when the claim is more thoroughly developed.

Boyle & Co. are running a tunnel below their summit claim on Humburg creek, which is now in about 500 feet, and will continue its extension until able to resume work at the summit, where the ground is covered with about eight feet of packed snow.

Work has not yet been commenced on the proposed tunnel into the old Spencer mine on Humburg, nor the contract let, but as soon as the weather permits, the bids will be considered and arrangements perfected for operations, probably about the 1st of April. The facing for the tunnel has been blasted and a shed built over the opening to same.

The weather has been quite cold for a number of nights past. It froze up the water supply in small streams and ditches and stopped mining in the placer diggings where sluicing was carried on; but the weather having moderated this week, operations have been commenced again with energy.

The Schroeder quartz mill on top of Deadwood mountain, about nine miles south of Yreka, has been shut down, on account of snow preventing an opportunity of hauling wood to the mill, run by steam. The snow is about ten feet deep on an average, some places 15 feet, and others where the wind has a good sweep, not more than four feet. Although there is an abundance of growing timber in the vicinity, it is impossible to move it through such deep snow. This extra quantity of snow, however, will be good for the summer season in supplying water, and unless we have warm rains and hot weather during the next two months, the mill may not be started again before the 1st of May in crushing a very large quantity of ore on hand, with more to be taken out every day, as the snow does not interfere with the underground stoping to any great extent, as the steep sides afford good drainage to prevent much dripping inside of the tunnels.

The Greenhorn blue gravel mine paid \$332.15 last week, and seems to be gradually improving. There is more water in the shaft and drifts to contend with since the storms of the past week, but not more than the steam pump can handle with ease. The surface supply of water is still greater in proportion, and very desirable for successful use in the sluices for washing the gold from the sticky gravel. Fifteen men are employed, working two shifts.

Yolo.

CALIFORNIA COAL.—A fine specimen of bituminous coal, said to have been found in Glenda valley, Yolo county, was taken to Woodland. It was very bright and hard and was deposited on slate to the thickness of an eighth to a quarter of an inch. When ignited with a match it burned steadily, showing that in quantity it would be most valuable.

NEVADA.

Washoe District.

ON THE COMSTOCK.—The following official letters of operations during last week have been received:

Sierra Nevada.—The south lateral drift from the intermediate tunnel has been advanced 16 feet; total length, 448 feet; face in very hard porphyry. The joint east crosscut near the north line from the north drift, 1520 feet west of shaft, 900 level, has been advanced 23 feet; total length, 90 feet; face in heavy clay.

Union Shaft.—The joint east crosscut, near north line from the north drift 1520 feet west of shaft, 900 level, has been advanced 23 feet; total length, 90 feet; face in heavy clay.

Potosi.—The south drift on the 450 level has been advanced 22 feet; total length, 156 feet. The drift has turned about six degrees east of south to follow the quartz. The east side of the drift is in quartz averaging from \$8 to \$12 per ton. The east crosscut, 300 feet south of the north line, 750 level, is out 174 feet, having been advanced 28 feet; face in porphyry. Are making repairs on 350 level.

Bullion.—The west drift from this station, 820 level, Ward shaft, is out 565 feet from the shaft; face in porphyry.

Ward.—The west drift from the station, 820 level, Ward shaft, is out 565 feet from the shaft; face in porphyry.

Alpha.—Are repairing the old Alta shaft.

Con. California and Virginia.—1650 level.—From the drift run north from the foot of the npraise on the sill floor of this level at a point 178 feet in from its mouth, a northeast drift has been advanced 38 feet in porphyry carrying fine lines of quartz. The crosscut running east from the drift run north from east crosscut 1 from the north drift from the winze (down 52 feet) has been extended 17 feet; total length, 45 feet; face in porphyry and a quartz formation carrying a low assay value. In working upward near the mouth of the east crosscut we have extracted 19 carloads of ore, about 19 tons, assaying \$30.25 per ton. Have continued prospecting work in the vicinity of the winzes 20 feet down. The npraise commenced at the end of the southwest drift, the Rule drift, from this 1000 station of the Con. Virginia shaft, has been carried up 44 feet and connected with the Best & Belcher drift. From the southwest drift at a point 343 feet south from the shaft station an east crosscut has been advanced 8 feet in quartz and porphyry formation carrying a low assay value.

Ophir.—1465 level.—The drift running north from the crosscut running west from the main north drift on the sill floor of this level at a

point 124 feet south from winze station, has been extended 16 feet; total length, 158 feet; face in porphyry, clay and quartz of low assay value. An advance of 72 feet has been made during the week in reopening and repairing the old Central tunnel, making the total length of the drift reopened from its mouth 686 feet. Have continued (jointly with the Mexican Company) the work of making repairs to the main shaft.

Mexican.—1465 level.—The crosscut running west from the drift run south from the top of the npraise which was carried up 46 feet above the sill floor of this level, at a point 40 feet west from the main north drift and 100 feet north from the south line of the mine, has been extended during the week 26 feet; total length, 256 feet; face in porphyry carrying clay separations.

Best & Belcher.—900 level.—The east crosscut which is being run on the north boundary has been extended 15 feet, passing through porphyry and seams of clay; total length, 153 feet, 1000 level.—The northwest drift from our main north drift, 102 feet from our northern boundary, has been cleaned and repaired 50 feet; total length, 350 feet.

Gould & Curry.—200 level.—West crosscut 5 started in northwest drift, 432 feet from the main west drift, has been extended 19 feet; total length, 907 feet; face in hard porphyry.

Hale & Norcross.—1300 level.—We continue stoping out ore from the winze below this level, and extracted during the week four cars of ore assaying \$29.75 per ton per car sample, and 26 tons of ore, average assay per car sample \$19.43 per ton.

Chollar.—The raise for ventilation from the 100 level to the surface is up 28 feet. Extracted and sent to the mill the past week 65 tons and 1200 pounds of ore from the 100 level. Milled during the week 78 tons; on hand at the mill 160 tons 1908 pounds. Average of battery assays, \$20.30; average in car sample assays, \$20.67.

Alta.—Since last report we have advanced the npraise 16 feet; face in quartz and porphyry carrying low assays. We have extracted about 8 tons of ore from the south slope, the average value of which, according to car samples, is \$42 per ton.

Silver Star District.

Ban Wathaa.—Hawthorne Bulletin: The severe weather of the past few weeks has made prospecting impossible. Those working under ground are all pegging away, with cheerful prospects.

Pedraza & Grasmis have about a carload of ore ready for shipment to the Hawthorne arrastra.

Frank Smith has a location on which the ledge crops out for the entire length of the claim. All the quartz carries gold, and samples have been found which show coarse gold in the quartz. As soon as the weather moderates Frank will begin sinking.

ARIZONA.

A NEW MILL.—Prescott Journal-Miner: The new 10-stamp mill at White Hills will be ready to start up now within a few days. The present mill consists of only 10 stamps, but 40 more will be added soon. This motive power for the machinery will be a gasoline engine, on account of the scarcity of fuel and water. Some idea of the richness of the property may be had from the fact that it is silver, and can be made to pay at the present price of that metal. The company has shipped carload after carload of ore which netted them \$15,000 each. A 60-stamp mill on a silver mine, in these days of low prices of silver, is a rarity. Chlorides are at work on other claims in the camp, and are taking out the richest ore ever extracted in that district.

RICH DISCOVERY.—Yuma Times: A letter from Harrisburg states that John Bullett has made a very rich gold discovery in the vicinity of Copper Camp, northwest of Vulture. The ore is as valuable as any found in the Harqua Hala. A party of Virginia City capitalists are on the ground investigating the property, with a view of purchasing. It is said that \$200,000 has been offered for the claim. The party is supposed to represent John Mackay, of bonanza fame.

LUMBER FROM ARAOAN.—Enterprise: A vessel loaded with 75,000 feet of lumber lately arrived at Gnamayas for the Bisbee Copper Co. Another vessel load of 441,000 feet will discharge in a few days, and is going into Bisbee as fast as convenient to hand.

OREGON.

Too MUCH SNOW.—Jacksonville Times, Feb. 22: The miners of Elliott creek have departed for the season on account of the snow, which is four feet deep.

A great deal of snow lies on the higher hills, which ensures a protracted run to those placer miners whose ditches head there.

It is reported that Alex Orme, the well-known prospector, has made another big strike in quartz in Foothills creek district, and has already taken out several thousand dollars.

The Annie mine in Bohemia district has produced many thousands of dollars during the past few years and is now turning out a ton of concentrates per day. There will be 150 tons ready for shipment when the snow blockade is raised.

A MALHEUR MINE.—Baker City Democrat: A porphyry formation that has attracted more or less attention from miners at Malheur City for several years past, but upon which little development work has been done on account of the low-grade character of the ore, is now in the hands of those who intend to investigate. Lately Mr. C. O. Barus of Ogden secured a bond on the property, and he in turn has rehired. The ledge or formation is fully 16 feet wide, and assays of the ore give a value of from \$6 to \$7 per ton. Arrangements are now under headway to commence sinking operations as soon as the weather will permit.

Electricity.

Heating by Electricity.

Mr. Campbell Scott, in a paper on this subject, remarks that such a quantity of electricity is necessary in operating electrical railway systems that the loss of a small portion of it is but a minor item to electrical railway managers, and from the start they showed an eagerness to adopt any method possessing so many conveniences as electricity for heating their cars and making them comfortable and attractive to their passengers. At the present time at least one-fourth of the electric railways of this country have their cars heated by electricity, and from what I can learn a very satisfactory result is accomplished at but a very light cost.

The method employed is very simple, which is as follows: Underneath the seat of the cars, in three or four locations therein, one of these electric heaters is placed and a small portion of the electric current used in operating the motors of the cars is diverted through the heaters. The general method employed in this new form of heating device for heating cars is as follows: The frame of the heater is generally about 8 or 10 inches high, about 6 inches thick and 3 feet long. A special "plaster" is made, looking something like porcelain when hard, in which very fine, specially prepared wires are embedded from one end to the other in zigzag fashion. The entire surface of the plaster is in this way embedded with the resistance wire, with the two ends of the wire protruding at one end, while in some cases several plates of plaster with these wires embedded therein are employed, after which the plaster substance is applied to the exposed surface of the wire, thoroughly encasing them therein. After this has been done, the whole substance is cooked until it resembles the hardest porcelain, with enamel finish. The exterior metal case, with legs underneath, is placed around this, and with sundry finishing touches we have an electric stove or heater.

It must be understood first, before I describe the method by which the heat is produced through the above mentioned medium, that electricity always flows in what is technically known as a "circuit," i. e., the electric current after being developed from a generating source, must return to the same source. In other words, electricity will not flow or operate unless this circuit is maintained, for as soon as the circuit is broken the flow ceases. Any metal will conduct electricity to a greater or less extent, but some metals possess the capacity of conveying a given amount of electric current with a far less loss than others. When we attempt to convey electricity through a bad conductor, we seem to "cramp" the electric current, and it seems that a great friction takes place therein, which causes heat. In other words, when an electrical conductor retards the passage of the current the conductor is heated and the greater the resistance offered by the conductor to the passage of the current the greater is the intensity of the heat produced. Copper is considered one of the best conductors and offers but little resistance to the flow of the electric current, while such metals as platinum, German silver, etc., are termed poor conductors, and on this account offer great resistance to the current's passage, and consequently in them the current produces heat. In electric heaters above described, very poor results would be obtained if the wires employed therein were composed of copper, which offers a very low resistance to the passage of the current, while the best results are obtained from fine, specially prepared wire, which offers a very high resistance to the current's passage and consequently causes the production of heat. This special resistance wire being embedded in the plaster is practically protected from the

outside air, and a very high heat is produced, which is conveyed to the enamel, the intensity of heat being governed by the quantity of resistance wire employed, also by the quantity of current which flows through it. For several years a number of inventors have been at work endeavoring to so perfect this system of heating that it will be available for many of the commercial and domestic uses where small heated surfaces are necessary.—American Gas Light Journal.

Light Without Heat.

To the speculative mind none of the possible future applications of electricity is more attractive and none so full of immediate interest, as the possibility that seems almost within our grasp of obtaining light without heat, or making the light waves without the heat waves that have thus far always been at the same time the companion and the burden of all artificial light, says the *Electrical World*. The time is ripe, and the exact science of the day seems all but ready and willing to give the analysts of two great problems, the answer to either of which would stand the crowning achievement of a century of progress in the application of nature's secrets to the requirements of daily life. One of these—the navigation of the air—seems to be a mechanical problem only; while the other—the production of light without heat—we may confidently say is only a question of properly handling the electric current. Nature presents us with beautiful examples of both solutions, but guards jealously the key to her method of operation, by which well-known forces are made to do the apparently impossible thing, and it is equally beyond our science to-day to explain how the bird soars aloft on motionless wings and how the glow worm emits a gleam of light without a ray of heat. But they do it, and the many imitators of the bird will soon be equaled in number by those who are chasing the fire-fly's secret.

What nature does with nature's forces man should and doubtless will be able to do with a full knowledge of those forces and a better comprehension of the methods by which nature applies them. Who shall say which is the more difficult accomplishment, the production of an artificial ruby or the production of an artificial light without heat? There is no certainty, indeed, that the latter will come from the hands of the chemist first. We are not only too prone to hastily write that down as the impossible which is simply not yet done and our last achievement as the most difficult of all accomplishments. Let us not, however, forget that the chemist has striven for more than a century to make the artificial stone with commendable success and the mechanic has striven a century to navigate the air, while the electrical engineer has wrested but a comparatively short time with the problem of light without heat and has already shown that the solution, far from being impossible on the lines of his attack, is, indeed, a reasonable expectation of another decade of electrical advance.

Complimentary Samples.

Persons receiving this paper marked, are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

REMOVAL.

The Clayton Air Compressor Works have removed their Offices and Salesrooms from 43 Dey Street to Second Floor of the HAVEMEYER BUILDING, Cortlandt, Dey and Church Streets.

For Catalogues, Estimates, etc., call or address

Clayton Air Compressor Works,
26 Cortlandt St., New York.

THE GRIFFIN MILL

The Only Perfect Pulverizer

OF
QUARTZ,
GOLD
OR SILVER
ORES,
PLUMBAGO,
PORTLAND
CEMENT,
OF
PHOSPHATE
ROCK,
FOUNDRY
FACINGS,
And All Other
Refractory
Substances.

Will work either wet or dry, and deliver a finished product. Capacity, 3 to 4 tons per hour on Phosphate Rock, 1½ to 2 tons per hour on Portland Cement, Quartz or Ores, depending on hardness of material to be pulverized and fineness of product. Grinds from 30 to 250 Mesh with equal facility.

NO JOURNALS IN GRINDING CHAMBER. BALL RIGID ON SHAFT HAVING DIRECT POSITIVE ACTION ON MATERIAL. MINIMUM POWER PRODUCES MAXIMUM AMOUNT OF PRODUCT. IT IS ABSOLUTELY GUARANTEED IN EVERY RESPECT, BOTH AS TO CONSTRUCTION AND CAPACITY. FIRST COST, WEAR, AND OPERATING EXPENSE MUCH LESS THAN STAMP MILLS. LARGE NUMBER OF MILLS IN USE ON DIFFERENT MATERIALS WITH POSITIVE SUCCESS IN EVERY INSTANCE.

Correspondence solicited, and illustrated descriptive pamphlet furnished on application to

BRADLEY FERTILIZER CO., 92 State St., Boston, Mass.

Double-Acting Cornish Plunger.

PUMPS TWICE AS MUCH WATER AS THE OLD PLUNGER.

AN ENTIRE NEW SYSTEM OF PUMPING.

Weight of Machinery Reduced One-Half, besides doing away with heavy balance bobs often carrying from 25 to 50 tons of balance. Works with 25 per cent less power. First outlay about one-third less. Suitable to any under or downright shaft. Friction reduced to a minimum. Occupies less space in the shaft. Has been tested about a year and proved to work satisfactory in every respect.

GUARANTEED TO GIVE SATISFACTION.

Special attention is called to this new feature in the drainage of mines and raising water generally, by which a continuous discharge of water is produced on the up stroke and down stroke, instead of on the down stroke only, which is effected by very much less than one-half the weight of machinery now in use.

When the ordinary pump becomes too small for the work it can be replaced by the new one, using the same rod and column, and doubling the discharge of water, a most important advantage in small shafts where there is not room for a larger pump.

Market Reports.

The Markets.

SAN FRANCISCO, March 1, 1894.

The course of silver during the week has been downward, the lowest point being touched last Friday, when the New York price was 59 1/2. There has been a somewhat better feeling since, and prices have slightly improved. The New York price today is 60c; London, 27 1/2d.

New York Prices.

Mining Share Market.

SAN FRANCISCO, March 1, 1894.

Last Saturday the Comstock shares closed weak, with sales of Con. California at as low as \$2.75 and Ophir at \$1.85, but Monday morning the whole list opened with a steadier tone, and afterward prices again took the up grade. Later the market acted as if it had been freed of a large number of weak margin accounts, and had a big accumulation of shares.

Tuesday there were further advances. Brokers bought freely. The stocks most in demand were Con. California, Ophir and Mexican, of the north-end group of mines, Potosi, Bullion and Chollar, of the middle group, and Crown Point, Belcher and Yellow Jacket, at Gold Hill. Relieved as it had been by recent heavy sales of weak margin stocks, and with a large short interest involved, the market readily responded to the sudden demand, and during the morning Con. California sold at as high as \$3.55, Ophir \$2.30, Mexican \$1.50, Potosi \$1.10, Bullion 40 cents, Belcher 85 cents, Crown Point 65 cents and Yellow Jacket 85 cents, with the other stocks higher in proportion.

Wednesday there was considerable activity in the market. After a strong closing last night the leading stocks opened at still higher prices in the Pacific boardroom this morning. At the first session of the San Francisco Board there was a sudden and unexpected break which could not be explained otherwise than that it was the result of the whims of speculators. Immediately afterward the leading stocks had a sharp advance. These erratic changes are evidently caused by the trade of the general public, who are now entering the market freely, and are easily scared or encouraged by the fluctuations.

—M. Cohn, Charles Kelley and other leading Carson merchants have combined and propose to put on freight teams between Carson and Sacramento. They say the steamers will land freight in Sacramento from San Francisco for \$2 a ton, and with the assistance of steam wagons, they can haul seven or eight freighters to the foot of the Kingsbury grade, via Placerville, then teaming to Carson can land freight there for one cent a pound. It is proposed to erect a big commission and storehouse, which will be stocked to draw on during the winter, when the roads are impassable.

List of U. S. Patents for Pacific Coast Inventors.

Reported by De & Co., Pioneer Patent Solicitor for Pacific Coast.

FOR THE WEEK ENDING FEB. 20, 1894.

515,285.—COLD STORAGE.—Burnham & Meyers, S. F.	515,072.—FRUIT BASKET.—T. Cogswell, San Diego, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

CAN BODY MAKING MACHINE.—Clarence M. Symonds, San Francisco, Cal. No. 515,136. Dated Feb. 20, 1894. The object of this invention is to provide an apparatus into which the sheets of tin are delivered and by successive dies are first bent into a semi-circular shape, and then have interlocking hooks formed upon their edges, after which they are still further bent until these hooks interlock and are closed together to form a complete can body, after which the completed body is moved outwardly and passed through a soldering bath after having the acid applied to the edges, so as to form the can body from the sheet of tin in a single continuous operation, the object being effected by means of an interior reciprocating horn having various portions of its length suitably formed to carry out, in conjunction with the dies and other parts, the various parts of the operation.

AUTOMATIC GRIP OPENER.—William F. Courtney, assignor of one-half in Albert Brown, Oakland, Cal. No. 515,115. Dated Feb. 20, 1894. The object of this invention is to provide a mechanism whereby the grip employed upon cable railway cars is automatically released at the point where the car crosses another cable line, and where it is necessary to temporarily let go of the cable by which the car is propelled. It consists of a vertical detent, a pitman connected with and adapted to operate the detent, a lever and safety bar, a pivoted link connecting these parts with the detent operating pitman, and a fixed anti-frictional incline forming contact with the lower end of the safety bar so as to force it upward, disengage the detent, together with a spring-actuated catch in holding the parts in the elevated position, and a foot rod for returning them to their normal position.

COAL HANDLING BOCKET.—William G. Curtis and John B. Isaacs, San Francisco, No. 515,117. Dated February 20, 1894. This invention relates to improvements in buckets, such as are employed for hoisting coal, dredging and other similar purposes. It consists of a bucket formed in segmental sections having coovering suspending rods coconnected with the outer and upper angles of the bucket, a shaft above the lower angles and coovering connections therefrom to the inner angles, together with independent pulleys loosely journaled on the shaft, and a single pulley mounted on a pivot which unites the coovering suspending rods, together with a shackle of rope connecting with the upper ends of the rods and a rope or chain around the pulleys so that the hoisting and closing and opening and discharging of the bucket may be performed with a simple operation and two ropes.

CHAMBER OR OTHER LIQUID RECEIVING VESSEL.—Jacob D. Rush, San Diego, No. 515,131. February 20, 1894. This consists of a closed vessel having an inclined ledge below the top, an inclined receiving plate supported upon the ledge with an encircling rim to confine and direct any liquid deposited therein, and an opening in the lower side in proximity with the adjacent wall of the vessel with a flange projecting from the wall directly under the opening to direct the flow down the side of the vessel.

Coast Industrial Notes.

—A portable sawmill is being put in above Elk City, Or. Its capacity is 400 feet a day, and it will fill some alder and cedar contracts already made with San Francisco.

—Horses which formerly sold for \$50 and \$60 in Harney valley (Or.) are now sold for \$25. Recently a band were sold for \$10 a head to a man without money, to be paid for in two years.

—An Oregon speculator recently purchased 6400 acres of valuable timber land in Nebahem valley. The price paid for it is stated at \$72,000. This is the largest land sale for some time.

—Work on the Esquimalt fortifications near Victoria, B. C., will begin at an early date. Arrangements are now being made for a number of teams for hauling dirt and rock on the excavations.

—The Canadian Pacific has let a contract

for building 250 miles of railroad between Nelson, B. C., and a point near Calgary. The proposed route is the much-talked-of Crows' Nest pass and Tobacco plains.

—Artesian water has been struck in Cochise county, A. T., by a man named McRae. The flow is 21,000 gallons in 24 hours. In addition to the value of the water, McRae will get \$2000 reward offered by the Supervisors for a running well not more than 500 feet deep.

—At the Sisson hatchery no less than 8,500,000 young fish have been hatched this season. About 6,500,000 still remain on hand, and will be kept until they are a year old. Trout hatching will soon commence, and it is intended to handle this season about 2,500,000 eggs.

—A fire at Kelso, B. C., burned nearly everything on Front street, between Third and Fourth. On the north side of the street every building is burned. The Custom House was destroyed, but the records were saved. Several buildings were pulled down, and others were blown up with dynamite.

—During the year an average of 1,000,000 feet of lumber a month has been put out by Pasadena lumber yards for use there. This gives 12,000,000 feet for the whole year (10 December 31, 1893), which at an average price of \$20 per 1000 gives \$240,000 as the total expenditure for building material of this kind during 1893.

—The Golden Rule Bazar, the well-known establishment of Davis Brothers, at 718 to 722 Market street, is a mass of ruins. Fire destroyed it Monday night. The loss, which is nearly total in the bazar, is estimated by the firm at about \$250,000, covered by an insurance of \$176,000 in nearly all the local agencies. The building belonged to the Blythe estate, and was insured for about \$20,000. It is a total loss. The cause of the fire is unknown, but that it had its origin on the Geary street side of the building there is no doubt.

Cal. Debris Commission Notices.

THE CALIFORNIA DEBRIS COMMISSION having received petitions to mine by the hydraulic process from Daniel W. Albert in the Union mine, near Brownsville, Yuba Co., to deposit tailings behind dam in dry ravine; from Tautouo Oampo in the Oampo mine, near Brownsville, Yuba Co., to deposit tailings in old hydraulic pit; from J. M. Wetmore in the Herring Ravine mine, near Brownville, Yuba Co., to deposit tailings behind a dam; from W. W. A. Lemmon in the Ooruit Ravine mine, near Brownsville, Yuba Co., to deposit tailings behind a dam in the Letson ravine; from James Gordon in the Motor mine, near Brownsville, Yuba Co., to deposit tailings in old hydraulic pit; from Crane Bros. in their mine at Sharon Valley, near Brownsville, Yuba Co., to deposit tailings in old hydraulic pit; from the Spring Gulch Mining Co. in the Spring Gulch mine, near San Andreas, Calaveras Co., to deposit tailings behind dam in dry ravine; from Joseph Snow et al. in Snow Bros' mine, near Newtown, El Dorado Co., to deposit tailings behind a dam in Welch creek; and from H. B. Havens in the Green Meadow mine, near Glennco, Calaveras Co., to deposit tailings behind dam in dry ravine; give notice that a meeting will be held at Room No. 32, Flood Building, San Francisco, Cal., March 6th, 1894, at 1:30 P. M.

Assessment Notices.

GOULD & CURRY SILVER MINING COMPANY.—Location of principal place of business, San Francisco, California; location of works, Virginia, Storey County, Nevada. Notice is hereby given that at a meeting of the Board of Trustees, held on the 31st day of January, 1894, an assessment (No. 73) of Fifteen (15) Cents per share was levied upon the capital stock of the corporation, payable immediately in United States Gold coin to the Secretary, at the office of the Company, Room 80, Nevada Block, No. 309 Montgomery Street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the 31st day of March, 1894, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on THURSDAY, the 29th day of March, 1894, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Trustees, ALFRED K. DURBROW, Secretary. Office—Room 80, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

Union Iron Frame Battery.

The stamp battery is the most familiar mechanical appliance for crushing ores. From the crude and clumsy device of earlier times, it has been so improved and perfected that it still holds its own against other methods. Stamps can be depended upon for effective and reliable work. They are so simple that but little skill is required to operate them, as well as keep them in repair, having the advantage that if anything goes wrong with one, it does not stop the entire mill.

One objection urged against the stamp battery is the expense incurred in erection, on account of the millwright work necessary in framing and construction; requiring skilled mechanics, who, in many instances have to be sent long distances, involving much time and expense, even where timber is available for this purpose. In localities where suitable timber cannot be obtained, it has to be freighted a long way; this, in connection with the cost of framing and setting up, makes a very expensive mill. It is little wonder, therefore, that a substitute for the ordinary wooden frame battery has been so eagerly sought for.

The Union iron frame battery, herewith illustrated, is designed to obviate all such objections and meet fully the demand for a cheap and portable mill complete in itself, that can be put up without skilled labor—conditions of importance in many mining districts—and that can be depended upon for the best results. In general construction, as will be seen, it is the same as the most improved form of battery intended for woodwork.

The mortar used in this battery is the latest improved standard mortar, being securely fastened to the mortar block by holding-down bolts. The columns are made of channel iron, to which the top bridge-tree, cam-shaft boxes and base piece are securely bolted or riveted, combining strength with durability and neatness of design. The mortar block, the upper section of which is shown in cut, is the same as that required for any other style of battery. It is ordinarily eight to ten feet in length and made of two-inch plank, spiked and bolted together. This makes a good block, and, in localities difficult of access, can be easily transported on either mule-hack or otherwise. When made in sections, the mortar is cut into six pieces or more, of full packing weight, and provided with reamed bolts for fastening together when in place. The mill being complete, no millwright or other skilled labor is necessary in setting up. The pieces are so marked that any one with ordinary intelligence can easily and quickly put it up in good running order. A single battery of five stamps makes a perfect mill. When larger capacity is wanted, any additional number may be added, making a 10, 20 or 40-stamp mill as desired. As may be mentioned, the Union Iron Works has furnished 100 stamps of this design to the famous Compania Huanchaca de Bolivia.

Although adapted to any locality, they have come more especially into use in Mexico, Central and South America, where facilities for securing available timber and having it framed are limited.

THE California Debris Commission last Tuesday granted the following permits to mine by the hydraulic process:

Crane brothers, mine at Sharon valley; J. M. Wetmore, Herring Ravine mine; Fausteno Campo, Campo mine; D. W. Albert, Union mine, and James Gordon, Motor mine. Application for permits have been made to the Commission by the owners of Spring Gulch mine, near San Andreas; Green Meadow mine, near Glencoe, Calaveras county; the Grub Flat, Badger Hill and Indian Hill mines, in Plumas county; the Spanish Hill Hydraulic,

A MODERN IRON FRAME BATTERY.

Spanish Hill Gravel, near Placerville; and the other mines in that neighborhood. Restraining works have been erected in the Kate Hayes mine, a large property at French Corral, and the mine is now ready for inspection by the Commission. This is one of the largest mines that has so far come under the authority of the Commission.

AUSTIN, Lander county, Nevada, now has about 400 people. Its bullion output does not exceed \$10,000 monthly. It once had 10,000 people. There is a vast amount of low-grade ore in the mines of that district, and if silver is ever placed on a parity with gold Austin is likely to again become a flourishing town.

The Miners' Wage Controversy.

The letter of a recent correspondent in the PRESS has started a discussion throughout the State as to miners' wages and their reasonableness. It seems to us that the question scarcely admits of argument, so far as California is concerned. The scale of wages in this State—\$2 50 to \$3 for underground work—is low enough, considering the nature and risk of the work, and the experience and intelligence required. As long as gold mines are generally prosperous, no uniform effort on the part of owners to reduce wages is to be expected, even when there are many unemployed miners flocking in from the silver States. It is true that in special instances, advantage will be taken of circumstances, or circumstances will require that the scale be reduced; but there will be no general movement, for the sufficient reason that labor of the character necessary to the best development of the mines cannot be secured for less. Besides this, the equities of the situation demand that the present standard be maintained, and herein is exerted no small influence upon owners, no matter what may be said or thought to the contrary.

The situation in the silver States is different. There is at present a strike in Cripple Creek—a gold camp, by the way—arising out of the demand of the miners' union for \$3 for eight hours work. In the nature of things, the miners have the losing end of the fight. On the Comstock wages are \$4 per day, and, owing to the strong stand made by the miners' union, are likely to remain at that figure for some time. The circumstances are exceptional. The number of men employed is new comparatively small. In the Coeur d'Alenes the strike was a failure, and employers pay what they please. But the mines are not running at all now, owing to the low prices of lead and silver. In Montana and elsewhere it seems to us that the tendency is toward the California basis, and it seems likely to take a decided turn in that direction before very long.

A CORRESPONDENT of a Grass Valley paper takes occasion to attack the State Miners' Association in the following, among other things: "Secretary Ralston, while not in any sense a 'mining man,' understands the work of fixing things so as to keep in his salaried office, and Jacob H. Neff stands by his friends through thick and thin. It is, indeed, a happy family, and your quartz miners ought to be ashamed for not putting their hands in their pockets and helping keep up the parade." Mr. Ralston makes a complete reply to this and other

criticisms in a recent issue of the *Tidings*, and shows that the Miners' Association has for its purpose the advancement of the interests of all branches of mining. Large attention has been paid to hydraulic mining, because this interest was suffering most severely. But the bill recently prepared by the legislative committee of the association and just introduced by Congressman Newlands, discloses that quartz-mining interests are looked after with equal care and diligence.

THE big push plow which was in the wreck near Truckee during the snow blockade has been hurned. This was found necessary in order to remove the disabled engine.

THE miners' strike at Cripple Creek is said to have been partly won by the miners. A dispatch from that place March 6th says: The Gold King, Strong, Granite and Washing mines have resumed operations on eight-hour shifts. The miners are sanguine of compelling every mine in the camp to adopt the eight-hour law. The Anna and Lee will commence work in a few days on the miners' terms. This news seems surprising, for the miners certainly had odds very strongly against them.

SENATOR STEWART is on deck in Congress with the free-silver cause. He has indicated his purpose to renew the fight. The Senator's persistence deserves admiration. Besides, it will be beneficial. The sentiment of the East appears to have been materially modified in relation to silver, and there can be no doubt that the single-standard advocates in Congress will soon be more ready to give greater consideration to the white metal. We think the signs of the times indicate an organized effort to secure the larger use of silver. Just what steps will be taken it is not possible to say.

A WASHINGTON CORRESPONDENT says that Oregon, Washington and Idaho, together with several other Western States, may receive federal aid to establish schools of mines. A bill for that purpose passed the Senate early in the session, but as it gave to each State a considerable quantity of land, it ran up against a snag in the public land committee of the House. That committee returned an adverse report February 8th, the result being the indefinite postponement of the measure. The friends of the bill in the Senate, however, were not content that it should meet with such a premature death, and, by individual solicitation on the floor of the House, succeeded in obtaining a reconsideration. The bill now takes its place on the calendar, and, as nine Western States are interested in it, strong efforts will be made to secure its passage.

JUDGE HAWLEY, in the United States Circuit Court of Nevada, decided in favor of the Sutor Tunnel Company the case of Symmes vs. the Union Trust Company of New York. Every point was decided in favor of the tunnel company and every act of Adolph Sutor was upheld by the Court. Judge Hawley said: "There was no fraud, and the board of trustees advised at all times, and Sutor's fee of \$100,000 was not exorbitant, as talents of a superior order were required. All the stockholders of the company had been fully notified of every step of Sutor and they could have protected their shares had they so desired." The decision involved the review of 5000 pages of testimony, 800 pages of briefs and 200 pages of pleadings. The Judge reviewed all the evidence and quoted numerous authorities on every point. He commenced his reading in this case last July. The delivery of the opinion occupied three and one-half hours.

Assessment Work Suspension Again.

It might have been expected that the suspension of assessment work on unpatented mineral claims by Congress for 1893 would lead to agitation for a similar dispensation during the present year. Petitions asking for the re-enactment of last year's law are now being circulated in Idaho, and are being numerous signed and forwarded to Congress. It is argued that if conditions rendered the suspension justifiable in 1893, exactly the same reasons ought to prevail in 1894. The silver mining industry is in a condition even more deplorable than a year ago, and mineral land claimants are more than ever unable to carry out the requirements of law.

There will probably be no very serious objection to granting the petition of the miners. It therefore seems altogether probable that Congress will take a generous view of the situation and re-enact the law. Indeed, it is not at all unlikely that the whole matter of assessment work on unpatented claims may be opened up and a serious effort made to abolish the requirement altogether. It is a fact well known that the law is more honored in its breach than in its observance, and that, in a great many instances, it wholly fails to carry out the purposes for which it was enacted, viz.: the enforced development of mining properties and the prevention of consolidation in the hands of one person the possession of many idle claims. It has, indeed, proved a factor in accomplishing the latter design, to a greater or less extent, but it is the pretty general conviction of mining men that some other statute might be more effective and satisfactory both to the government and to the miner who is not a speculator. It is believed by many that the mining laws of Mexico, requiring an annual rental, are an improvement over those of the United States. The rental could be small—say \$25 or \$50—and the proceeds in each district comprise a fund which might be used for the benefit of the district.

There are other considerations affecting the title to unpatented claims which are a powerful argument for improvement of the present law; but they do not need to be discussed here. It is sufficient to repeat that there should be some more definite method of requiring an annual expenditure on mining claims, or an equivalent thereof. Under present conditions there is no adequate method of verifying the simple assertion or affidavit of a claimant who says he has performed assessment work of the value of \$100; and, likewise, it is difficult and generally impossible to bring forward proof to dispute his claim.

If Congress does pass the relief measure for 1894, it is to be hoped that its intentions may soon be indicated. Last year, when the act was passed, very many claimants in California and other States and Territories had already complied with the law, and so the suspension was of no benefit to them. To be sure, they did not begrudge the relief afforded to those who needed and secured it, but it is not unreasonable to ask that action be taken early enough to make the law, if it passes, general in its operation, and to allow them to take advantage of its provisions if they desire. The matter should not be left in doubt.

The Anti-Debris Agitators Again.

Several events of interest to hydraulic miners have occurred during the past ten days. The Anti-Debris Association, resenting recent statements that appropriations from the several river counties for its maintenance are now given with reluctance, attempts to bolster up a staggering cause by securing passage by the Sacramento grand jury of a resolution declaring its undiminished confidence in the Anti-Debris Association and its work. The anti-debris people complain that their spies will have more than they can do with the coming of spring; and they declare that at least two mines are operating illegally. The only real sign given by the Association of a genuine intention to carry out the purpose for which it was organized and is maintained at public expense is in the shape of instructions to Attorney Devlin to take the necessary steps to prevent illegal mining. So far as it acts within the law, this step of the association, if carried out, will be supported by miners generally. The State Miners' Association has honestly attempted to discourage and suppress unlawful mining; and its attitude now is precisely what it has been. That is, it will not countenance infraction of the law. A way has been opened up by statute for the resumption of hydraulic mining, and it is the desire and purpose of miners generally that every effort be made to comply with the law and start the mines under its provisions. The miners have been disposed to give the Caminetti Act a fair chance; some of the anti-debris people are not. There is the difference.

One of the other entertaining features of recent occurrences is the attack of the Marysville Democrat, a hide-bound anti-debris organ, upon the river improvement

delegation recently sent to Washington, and incidentally a declaration of its confidence in the practicability and value of restraining dams. The Democrat is anxious for the construction of the proposed dam at Deguerre point, because "it is a necessary starting point of an engineering system for improving these rivers" (Sacramento, Yuba and Feather). The Democrat objects to Mr. Ohleyer particularly, because he is opposed to dams on general principles, and is particularly not in favor of a restraining wall at Deguerre point. The paper says further:

"But we are aware that there are a few men who place their own judgment against that of the Government engineers, men who consider themselves competent to dictate to those who are authorized by the votes of the people and by law to act in such cases. Such men are obstructionists, who chain the wheel of progress, and should be relegated to the rear and placed on the retired list."

These things may be taken as substantial proof of the declaration, several times made in these columns, that the old valley prejudice is greatly weakened and even dying out. The real sentiment of the valley—real, because intelligent—is that restraining dams fully protect their interests. It is well known by all residents of the Sacramento valley that the California Debris Commission is an impartial body whose duty and purpose are to protect the farmer. The Commission has said full security is afforded by restraining dams properly constructed. The declaration of the Commission deserves absolute credit. Only the professional agitators pretend to be alarmed for the safety of the residents of the valley. They have been waving the bloody shirt of warfare on the miner for so many years that it is impossible for them to break up the habit. Their next move, perhaps, will be to ask the State for pensions because of their long, arduous and heroic efforts in behalf of the "cause," and their invincible ignorance of the palpable fact that the war is over.

As an illustration of the popular method of expression by the chronic opponents of hydraulic mining in any guise, the following from the Sutter Independent may be given:

"Just kill off the [Anti-Debris] Association, retire the watchman and say let the Caminetti law take its course, and soon clandestine hydranlicking will be going on all over the watershed of the Yuba and Feather where it can be prosecuted."

In other words, the Independent means to say that the Caminetti Act is totally inefficient, and that the true policy of the farmers is to place their welfare, their safety and their prosperity in the hands of a self-constituted organization which is superior to the law and is better able to kill off the miner and exalt the farmer than the Debris Commission, the law or the courts. The Caminetti Act undoubtedly might be improved, and, we think, will be. We have no expectation that the policy of the law will be changed in the near future, and we think that the conditions under which hydraulic mining may be carried on are definitely fixed, and are likely to remain the same for many years to come. But there are several features which need correction. They will doubtless receive the early attention of Congress. It is not to be doubted that the Caminetti Act is backed by public sentiment, and for that reason, if for no other, we think the true attitude of the Anti-Debris Association is to give the Debris Commission its support, endeavor to secure enforcement of the law, and determine fully whether or not all interests are conserved by its operation. If they are not, the repeal of the law, or an adverse decision by the courts, will be certain to follow. If they are, a happy and satisfactory solution to the whole problem will have been found.

The Debris Commission, through Colonel Mendell, its president, suggests that Section 12 of the Caminetti Act be changed. At present, one clause reads:

"Pending publication thereof said Commission, or a committee thereof, shall examine the mine or premises described in such petition."

The Commission suggests the following:

"Pending publication thereof, or as soon thereafter as practicable, the mine and premises described in the petition shall be examined by one or more members of the Commission or by an engineer acting under its orders."

The proposed change is self-explanatory.

Foundry Notes.

THE Perkins Pump and Engine Company has been incorporated. Capital stock, \$50,000, half of which has been subscribed.

THE Keystone Boiler Works is constructing a boiler for the whaler, Wm. Baylies. The Baylies is being converted from a bark to a steamer. The total number of steam whalers leaving this port is now thirty-two.

REPRESENTATIVE HILBORN has introduced a bill in Congress making an appropriation of \$100,000,000 to provide for the erection and equipment of a gun factory at Benicia, Cal., for finishing and assembling ordnance for the army and navy. The bill provides also that this gun factory shall be erected upon the United States Reservation at Benicia, Cal., under the joint direction and supervision of the Secretary of War and Secretary of the Navy, and upon its establishment shall be placed under the joint and equal control of the Bureau of Ordnance of the Navy and Ordnance Department of the Army.

California Mines at the Midwinter Fair.*

California makes the most varied and complete display of its vast mineral resources at the Midwinter Exposition ever before attempted to be collected. The central ideas of its projectors were massiveness, richness, attractiveness and completeness; and in each of these particulars most satisfactory success has been achieved. It is, in the first place, the largest California exhibit ever made; in the second, it comprises the most valuable specimens; third, the arrangement is most tasteful and artistic and the specimens and various other features have been selected with great good judgment; fourth, the several branches of the mineral industry are adequately represented. Besides the mineral exhibit proper, there are shown in the vicinity different mechanical and chemical appliances for reducing ore, from a complete cyanide outfit to a five-stamp mill; from a primitive pan and long tom to the modern hydraulic giant. The exhibit, as a whole, possesses the rare merit of being interesting to strangers who know nothing of mining, and who by this means have been made to understand its processes and perhaps to retain a permanent interest in the industry.

The location of the exhibit is in the Mechanic Arts building, where it occupies about 10,000 square feet of ground space. It is not too much to say that it is the most conspicuous display on the floor. Visitors are numerous, and their expressions are uniformly complimentary. It is the design in this issue to mention the displays of El Dorado and Tuolumne counties, which are now complete.

El Dorado County.—The display is just to the left of the aisle leading from the main entrance of the building to the grand court, and it occupies about 600 square feet. The most conspicuous feature of the exhibit is a fine model, heroic size, of the celebrated J. Marion Wells bronze statue of Marshall, discoverer of California gold, erected at Coloma, El Dorado county. Its place is in the center, the base being covered with a great variety of ore and other mineral specimens. Entrance is effected through a slate arch 14 feet in height, from the Chile Bar quarry, 2½ miles north of Placerville. Specimens of slate from the quarries of the San Francisco Slate Company and of Jacob Stahl are also shown. Good specimens of white and mottled marble, from undeveloped deposits, are shown. A specimen of Indian Diggings marble is particularly clear and white, and is said to be equal to the best Inyo county marble. A fine block of sandstone from Pleasant Valley occupies a prominent place. A singular feature is the clear marking of the strata, which are distinctly black, red and white. The sandstone is said to be durable and able to resist the action of heat. A block of lava from Diamond Springs shows out in relief the name of "F. L. Lepetit, 1857." It is very well preserved, and amply proves that the lava is useful for building purposes. Soapstone for fireplace and similar uses is also shown. It is from Darlington's quarry, Placerville. Unslacked lime, in a hermetically sealed jar, is exhibited by the H. T. Holmes Company. Specimens of chrome ore, which are found in several places throughout the county, are displayed, and copper from near Fairplay and Coloma. In the latter the virgin metal is very clearly visible. A case of crystals from Messrs. Swanborough and Blackstone, White Rock, attracts a deal of attention.

The usual specimens of ore from the various mines of the county appear in large number. One from the Oro Fino mine weighs 4000 pounds, and several specimens from the Idlewild range from 1600 to 2000 pounds. There is a very large number of quartz specimens in a case (from the Idlewild) the values of part of which, determined by assay, are as follows: \$850, \$111, \$73, \$45, \$42, \$56, \$66, \$32, \$94, \$318, \$34.50, \$23, down to 50 cents. The \$850 specimen weighs 15 pounds.

El Dorado being the scene of the original discovery of gold, it might fairly be expected that many interesting relics would be shown; nor is anticipation disappointed. Among other things are the first mortar and pestle brought to the State for the purpose of crushing quartz; saw used at Sutter's mill; candlestick, knife, tape line, hammer, gun and walking cane belonging to Marshall, and a square iron shoe to which is attached the following description:

This is a shoe from the first 10-stamp wooden steam quartz mill ever built on the Pacific coast. It was shipped from Nashville, Tenn., via Cape Horn, and erected by A. L. Ohlton and others on the Concomnes river, in the town of Nashville, El Dorado Co., Cal., on the old California Consolidated, or Nashville, mine, in the years '50 and '51. Attached to the cabinet of J. O. Head, Nashville, Cal.

The exhibit is in charge of George Hofmeister, Placerville, who is courteous to visitors and takes pains to make them understand the many merits of the exhibit.

A summary of El Dorado's exhibit is as follows:

Roscolite sulphurets and gold-bearing roscolites from the

Grube mine; gold-bearing quartz from the Gopper mine, Kelsey; gold-bearing quartz from Coloma; gold-bearing quartz from Georgia slide; gold-bearing quartz from the Pacific mine, Placerville; also from the St. Lawrence, Kelsey; also from the Banner mine, Kelsey; specimen pin worn by Marshall, discoverer of gold; bottle of gold from Sutter's millsite; specimens from the Cedarberg mine, Greenwood; also from the Logtown, El Dorado; also from the Irish Creek mine at Kelsey, the Mount Pleasant mine at Grizzly, and the Middle Fork mine at Spanish Dry Diggings; asbestos from Garden valley, ocher from Garden valley, marble from Indian Diggings, copper ore from the Mount Queen mine; crystals; magnesia and cinnabar from Greenwood; pebbles from Dutch creek; sulphurets from Slate creek and Irish creek, isinglass from Pilot Hill, chrome from Coloma, nickel ore from Burner Hill; specimens of quartz, gold, silver and sulphurets from the Adam's Gulch, Montezuma, Church-Union, Nashville, Gabriel, Stony Point, Inez, Wilson, Pacific, Harmon, Volcanoville, Kelly, Hog's Diggings, Bonider, Crystal, Darling, Stillwagon, Black Rock, Big Sandy, Vandergrift, Potts & Murdock, Breathe Brothers, Idlewild and Snow Brothers mines; specimens of black silicate, crystallized quartz, marble, agate, lime, pumice and a large number of relics and curios from the famous Sutter mill at Coloma; Indian relics, curios, utensils, beads, baskets and the like; a 6000-pound pile of Oro Fino rock.

Tuolumne County.—The main purpose of the collectors of this very attractive exhibit appears to have been to show at once the variety of Tuolumne's minerals and the rarity and beauty of their specimens. The location is on the north side of the north aisle, where the display occupies about 500 feet of space. It is not too much to say that the exhibit as a whole is in quality the inferior of none, and it has many admirers who say it is the most choice, unique and tasteful in the whole collection. In general, its features consist of a magnificent collection of specimens; ore from the various mines; photographic views of the different localities and mines of the county; and other mineral and wood products.

Entrance to the exhibit is through a triple arch of eugar pine, beneath which, on a marble slab, rest several big chunks of quartz from the famous Rawhide mine, the assay value of which is \$26,000 per ton. The total weight of these specimens is 1600 pounds, from which their probable value may be determined. The quartz is the well-known mariposite, and is from a 15-foot vein between a banging wall of slate and a footwall of serpentine and diabase. It may be said in passing that the Rawhide is one of the famous abandoned mines of California, which was idle for about 26 years. Stamped in its new mill have been dropping now for a year or more. The great value of the mine is absolutely known. Its owners are A. J. Nevills and Meers, Ballard and Martin.

A leading feature of the exhibit is a pyramidal and octagonal cabinet, containing about 1000 specimens representing 400 mines. The cabinet is in the center, and it is about eight feet high. It is made of 261 pieces of wood, containing 38 varieties, including poplar, laurel, sequoia, maple, redwood, manzanita, etc., all from Tuolumne county. It is the handiwork of Joseph Oneto, employed at the Sonora mill of S. S. Bradford. Its arrangement is such as to show to fine advantage the many gold specimens it contains. These were collected from a great number of owners for the special purpose of this display. They comprise nuggets, leaf gold, drift gold, cement gold, gold in tellurium, crystallized gold and very many others. One piece of quartz gold, from the Garrett mine, weighs \$768. From the North Star mine another is worth \$154. On one shelf are 261 pieces belonging to Mrs. Judge Preston of Jamestown. One specimen shows leaf gold in crystal, very clear and very beautiful. There are 38 pieces of crystallized leaf gold belonging to Thomas Reed of Graveland. From the Page mine at Bald mountain is an exceedingly rare specimen of cube gold in tellurium. A splendid crystal, about two inches in circumference, shows clearly inside leaf gold.

Among other things are several quartz specimens from the celebrated pocket mine of Tuolumne. Mr. J. H. Neale, who is in charge of the exhibit, tells of one instance where, from a pocket in the Bonanza mine, Sonora, 968 pounds of gold were pounded out in a hand mortar. The detritus was later milled; the total net return from this pocket being over 1000 pounds of gold.

On a shelf in the rear of the exhibit are displayed ore specimens from 400 mines. They comprise every variety of quartz. One specimen of hematite weighs 170 pounds and is valued at \$352. Above this collection are affixed 125 fine photographic views.

The exhibit is in charge of Mr. J. H. Neale, Midwinter Fair Commissioner from Tuolumne. Mr. Neale is assiduous in his attention to visitors. He was chiefly instrumental in collecting the exhibit, which, by the way, involved no small labor, and he knows thoroughly the history, character and value of all the many things shown. He is evidently the right man in the right place.

A brief summary of Tuolumne's exhibit is as follows:

Leaf gold, foliated gold, crystallized gold, placer gold, gold gravel, nuggets and river gold, worth in all between \$7000 and \$10,000, and from some of the four hundred and odd mines of the county; gold quartz from the following mines: Alameda, Arbona, App, Ajax, Antelope, Alta, Buzzard's Roost, Belcher, Basin, Buena Vista, Belle View, Badger, Black Oak, Crystal-line, Criss Cross, Carlotta, Carmelita, Confidence, Comstock, Crown Point, Duffield, Dutch, Consolidated Eureka, Golden Gate (sulphurets only), Gerryman, Homestead, Hibben,

Hunter, Isabella-Gem Consolidated, Joe Hooker, Kanaka, Knox & Boyle, Keltz-Kelvin, Laura & North Star, Louisiana, Little Wonder, Laborator, Live Oak, Lamphore, Mohawk, Mary, Monte Cristo, Monitor, Mina Verda, Mooney, Mullins, Never Sweat, New Era, Noonday, New Albany, Parole, Prudhomme, Palo Alto, Platt & Gibson, Porto Fino, Raglio, Red Jacket, Rawhide, Saulsbury, Seminole, Sweeney, Senorita, Spring Gulch, Santa Maria, Silver Queen, Sonora Extension, San Giuseppe, Stent, Violet, Two Brothers, Worcester, Wheel Perin, Trio, Webster, Carrie, Mary Ellen, Old Tuolumne, Marks & Darron, Gross, Gillis & Carrington, O. K., Lady Washington, Woodpecker, Somerset, Riverside, Draper, Nonpareil, Cosmopolite, Buchanan, Rappahannock, Bonita, Consuello, Shangkai, Mount Vernon, Sopbia, Simonitch, Sngarman, Golden Rule, Heslop, Eagle, Patterson, Starr King, Grizzly, Obapparat, Stanley, Our Flag, Bonanza. Other exhibits: Marble from Columbia, 12 varieties; gold-bearing gravel, 10 varieties; granite, chrome iron ore, manganese, irridium ore, platinum, hematite ore bearing gold; placer gravel and gold from the Stanislaus and Tuolumne rivers; photographic views of quartz mills, mines, tunnels and mining scenery in Tuolumne county; 125 pictures.

Slitkens.

The Morning Star Mining Company of Nevada county has declared its 38th dividend at the rate of \$4 per share.

GEORGE M. NORTON, a famous Colorado mine operator, is dead. He was once well known in California and Nevada.

The pay rolls of the Comstock mining and other companies for the month of February amounted to \$61,995.50, or \$3214.75 less than for the previous month.

A lot of mining property and some amalgam was sold by an Arizona Sheriff under two judgments aggregating \$425. At public auction the lot brought \$7.50.

While Leonard Redding was cleaning out an old drill hole in the Gold Hill mine, near Angels Camp, the dynamite exploded and blew off one of his hands.

REPORTS from Lettbridge, B. C., where the coal miners recently struck, say that there will be no trouble unless it is sought to put non-union men to work.

It is not at all unlikely that by fall 2000 to 3000 people will be living out on the desert in the vicinity of Goler, Kern county, provided water and gold both hold out.

RALPH NICHOLS, the successor of Colonel Thomas to the superintendency of the Sutro tunnel, has arrived on the Comstock and will assume the duties of his position at an early date.

THERE is in San Benito county a mine of good coal. The vein is six feet in width on the surface and increases with depth. It is said that the railroad company has made an offer for the mine.

The Consolidated California and Virginia Mining Company has levied an assessment of 50 cents per share, aggregating \$103,000 and delinquent April 10th. The last previous assessment was levied on December 13, 1892, and was of an equal amount.

SEVERAL gold, silver, copper and iron mines near Bozeman, Mont., have been purchased by George W. Ballou, who represents a syndicate of New York capitalists. The price paid was \$1,000,000. The mines will be extensively developed and large concentrating works erected.

THE Chairman group of mines, consisting of the Southern Cross, Obainman, Obainman Gore, Turkey and "V," have been bonded to W. B. Graham for \$350,000, says the White Pine News. The chances are that a sale will be the outcome of the negotiations now in progress.

THE Pomona Mill and Mining Company has been incorporated. Principal place of business, Pomona. Capital stock, \$2,000,000, with E. B. Smith, W. D. Smith, E. Henderson, P. J. Tarr and V. E. White of Pomona, M. Maxson of El Monte and E. E. Powers of Los Angeles as directors.

DURING a blinding snowstorm, John Cameron of Tuscarora fell into a shaft some 25 feet deep, and was rendered unconscious. When he recovered his senses, realizing that no one could hear his cries for help, he used his pocket-knife to cut steps in the almost perpendicular sides and reached the surface unaided.

THE Reno Reduction Works have been leased by Russell, Bradley, Foley & Co. for six months, with the privilege of naming them for a year. It is said to be the intention of the lessees to work 5000 or 6000 tons of the English mill tailings at the works. R. D. Clark, who is one of the lessees, will have charge of the works.

THE finding of a \$520 nugget by W. Elmore near Copley last week and the recent finding of \$105 at Quartz Hill by Thomas Harrison, calls to the mind of the Shasta Courier that on Spring creek some fifteen years ago Rocon and partners took out a solid gold nugget weighing \$1100 and smaller pieces and coarse gold to the total amount of \$3300.

THE executive committee of the Anti-Debris Association has elected the following officers: President, J. M. Morrison; secretary, Robert Cosner; manager, W. T. Phipps; attorney, Robt. T. Devlin. The following legislative committee was also elected: Hon. F. R. Day, Hon. George Ohlleyer, John C. White, Robert T. Devlin and W. T. Phipps.

THE directors of the Excelsior Water and Mining Company of Smartsville have elected the following officers for the ensuing year: President, W. G. Halstead; vice-president, Louis Conrath; secretary, Joseph Duffee; treasurer, W. G. Halstead; assistant treasurer, Louis Conrath; general superintendent, Louis Conrath; mining superintendent, J. N. Flint.

At the annual meeting of the Wyoming Consolidated Mining Company the following were elected as directors: J. H. Widder, J. H. Manor and E. H. Baxter of San Francisco, and B. F. Runnels, W. L. Wallace, W. J. Rogers and W. E. Parsons of Grass Valley. The board organized by electing B. F. Runnels, president; J. H. Manor, vice-president; W. E. Parsons, secretary.

THE directors' monthly report for December, 1893, of the Robinson Gold Mining Co. of Johannesburg, South Africa, shows that the mine turned out 8214 tons of quartz, which yielded 10,063 ounces and 8 dwts. of gold. The concentrates and tailings, worked by chlorination and cyanide process, increased this amount to 17,062 ounces and 12 dwts. This was the total output from their own ores. Besides this the company purchased large quantities of concentrates and worked them, and altogether they made a profit of £38,594, 10s., 11d.

*It was intended, in presenting this review, to write up first the exhibit as a whole before taking up the various counties. In one or two small particulars, however, it is not complete, and the appearance and character of the exhibit all together must be deferred.

The Law of Cross Lodes.

The California Supreme Court, sitting in bank, has just handed down its decision in the Grass Valley case of Wilhelm vs. Silvester, which for the first time in this State settled a long disputed point as to the right of locations of cross lodes. The case concerned the New Idea location near the Gold Hill mine on appeal from the Superior Court of Nevada county. It first came up before Department 2 of the Supreme Court, but was considered of such importance as to be laid over for a decision of the full bench. Before this full bench (or bank) it came up in Sacramento last November and has now been finally passed upon. Some of the State courts, notably Colorado, have held a different opinion, but, as stated, the matter has never before been passed upon in California. It is believed that the decision will have an important bearing on the Champion and Wyoming litigation now in the Circuit Court. Throughout the controversy A. Burrows represented Silvester, and Kitts and Bowman Wilhelm et al. The decision affirms Silvester's right to the ground and all veins within its limit, whatever their direction.

As reported in the Grass Valley *Tidings*, the contention in this case was one as to the proper construction of the mining laws of the United States. It is admitted that in 1879 the respondent only located the "New Idea Quartz Mine," the same being a parcel of land 1500 feet long by 600 feet wide, and that about one year after such location the plaintiff's, against the respondent's consent, attempted to locate a claim called South Scotia, which bisected the New Idea claim, taking in 600 square feet thereof.

At the time of said attempted location, the respondent's New Idea location remained a valid existing prior location, and the respondent has ever since its location complied with all the laws of the United States and local customs.

Plaintiffs claim that because they discovered a cross-ledge which penetrated the New Idea claim, that so much of the New Idea premises as was necessary to locate said cross-ledge became subject to location and that such cross-ledge thereupon became the property of the plaintiffs.

The defendant claims, under Section 2322, Revised Statutes of the United States, which gives him in terms: "The exclusive right of possession and enjoyment of all the surface included within the lines of his location and of all veins or lodes throughout their entire depth, the top or apex of which lies inside their surface lines."

The plaintiffs, Wilhelm et al., claim that Section 2322 has been modified by Sec. 2336 of the same Act, which says, "where two or more veins intersect or cross each other, priority of title shall govern and such prior location shall be entitled to all ore or mineral within the space of intersection for the purpose of convenient working of the mine; and where two or more veins unite, the oldest or prior location shall take the vein below the point of union, including all the space of intersection."

Silvester's attorney made the following points:

1. Section 2322, R. S. U. S., makes him the absolute owner of all the veins whose apex falls within the lines of his location. Section 2336 has no application to any location made under the Statutes of 1872, but applies only to the old style "ledge locations" made before 1872, and included no surface ground, but simply the lode itself. (*Eclipse vs. Spring*, 59 Cal., 304.)

2. There is not a single sentence in Sec. 2336 which confers any right to lode or ledge matter, on the junior locator of a mining claim, or recognizes a "location" on land not otherwise subject to location. The only right conferred on a subsequent locator is the "right of way." But there is no contest as to a right of way in this controversy.

To say that Sec. 2336 implies enough to repeal and abrogate the provisions of Sec. 2322 of the same act, relative to the "exclusive rights" of the first locator, is absurd and contrary to the rules of statutory construction. The statute protects the oldest locator of a ledge from any local rule that might deprive him of his vein below the point of union, but not confer any right on any other locator. Its object was to protect the senior locator as to the vein and a junior locator as to right of way, and it cannot be construed to intend anything else, so as to abrogate other express provisions of the same act.

In his opinion Sec. 2336 was never intended to modify Sec. 2322, but was meant to supplement Sec. 2320, where it fits in without any such torture, straining or inconsistency as must be adopted in attempting to apply it to Sec. 2322.

The act of 1872 applies to three classes of mining claims: (1) Those already in existence and known as "ledge locations," as regulated by Sec. 2320 (and also by Sec. 2336); (2) locations to be made under the said act of 1872 described especially in Sec. 2322; and (3) placer claims, described in Sec. 2329.

His theory of the application of Sec. 2336 was that it applies solely to the numerous ledge locations, which existed when the law passed, and that the attempted location

of South Scotia, by intruding on the side lines of the New Idea, was invalid so far as it included a portion of the New Idea, because not made on the public domain and also because it constitutes a trespass by virtue of which no right whatever could be initiated, and the provision of Sec. 2322 as to the exclusive right of the locator to the possession and enjoyment of all veins whose apexes are found to be within his surface lines admits of no exception whatever.

With this position the Supreme Court now concurs and affirms the judgment of the court below.—*Tidings*.

Ore Shipments from Shasta.

TO THE EDITOR:—I notice by the PRESS and by receiving new ore rates from the railroad company that freight on ore has been lowered. The conditions to be complied with are the principal objections to this reduction. The lowest rate given—that on \$50 ore—will not be used from this part of the State. It does not pay to send ore of less than \$50 value to smelters. Rates for the other values in carloads are much below the old rates. But from \$100 up, when the per cent according to weight and the per cent according to value is added there is little difference from former rates. This ore tariff says, in the absence of positive information as to the value of ore, the agent will bill high enough to protect the company, the rates to be corrected when actual value is produced. This actual value is to be found by "special assay" if the railroad company wish. They must then sample the ore to get the average before assay can be made.

Is there a miner whose manhood is so dead that he would willingly stand by and see the employees of the Southern Pacific sample his ore? This is done under the thin guise of protectlog the company.

The value given in the shipping receipt protects the company in law, and there is nothing else. Freight must be paid in advance, and after they, as carriers, have delivered the ore at the smelter, they can have it sampled and assayed for their protection! This would only be equalled by the Southern Pacific employees seizing a passenger at his destination and plundering his pockets to see how much value he had about him and readjust the amount paid for passage according to the value found on his person! Ore tariff No. 1 means that the railroad company are to be partners of every miner who is shipping high-grade ore on the line of their road, and gives them part of the proceeds; and as they own every other section of mineral land, they can find out whose land the miner is on and force him to buy it.

The railroad company having possession of all the odd sections of mineral land is the greatest detriment we have to contend with in developing our mines in northern California. The attention of our Congressmen and Senators should be called to this, and a committee appointed to come here and see that it is not such land as they are entitled to by law. They are selling this land, rich in mineral, as agricultural; when it is nothing but a mass of upheaved rock, the purchaser buying for the mineral only. A committee was appointed by Congress to go to Montana and Idaho to set aside mineral lands held by the railroad companies. Why not have one come to California?

Shasta, March 5, 1894.

JOSEPH E. BELL.

Carson River Dredge Plant.

For the information of inquirers as to the process whereby the Carson River Dredge Company expects to recover a portion of the wealth buried in the bed of that stream, representing the percentage of amalgam and quicksilver lost in milling Comstock ore, the *Enterprise* publishes the following description of the company's plant:

The steam dredge is operated on a flat-bottom boat or scow with a double deck, the lower deck or hold containing the machinery. This boat is about 80 feet in length. The dredge has a lifting capacity of several hundred tons in 24 hours. Another boat of still greater length is equipped with a double line of flumes or sluices. When the material is raised from the river bed it is discharged in the flume and is washed on the same principle as in placer mining. When it leaves the flume it flows over a line of Woodbury concentrators. Tests of these concentrators show that the sulphurets are concentrated to a high percentage above the value of the material in bulk.

The tests so far were made with two concentrators, and demonstrated that with a sufficient number of them, to handle the material as rapidly as it is raised by the dredge, a net profit of from \$1000 to \$1500 per day can be realized from the sulphurets after they have been run through the amalgamating pans. Next spring the company will have all the concentrators in position required to handle the material with the dredge operating to its full capacity. The entire cost of the present plant has been contributed by the shareholders in the Dredge Company, the stock of which is unassessable. They have been experimenting during the

past six years on the best method of recovering at least a part of the vast wealth from the river bed, and the officers are now satisfied that they have solved the problem.

For a Mines and Mining Department.

TO THE EDITOR:—In your issue of March 3rd you say, editorially, that State Mineralogist Crawford has informed the Associated Charities of San Francisco, in answer to their inquiries, that he is unable to give them any information about placers in this State which could be worked by the unemployed. This statement illustrates the need of a thorough and systematic digest and comprehensive bureau of authoritative information in regard to this great and distinctive department of the Nation's economy, and justifies, in a striking way, the action of the Trans-Mississippi Congress, while in your city recently, in passing a resolution recommending that the United States should enact a law creating a Department of Mines and Mining, similar to that of Agriculture.

Were there such a department in our National Government, the mining lands could be so tabulated that the appropriated, the unappropriated, and the abandoned mines would be known and easily designated. Then, in the event of hard times, such as we are now having, the unemployed citizen, with little assistance, could be got upon them and be enabled to make a fair competency, if not a fortune, for himself.

The Government of Australia, by reason of its having a Mining Department, has, during the last year, given work to several thousands of the unemployed in her mines, and the plan has worked admirably, as well as beneficially.

The county of Siskiyou, which is nearly as large as the entire State of Massachusetts, has many thousands of acres of unappropriated mineral lands, and many abandoned mines, which could be made to yield a livelihood to the unemployed citizens of the United States, were there only some National bureau to properly formulate rules for their guidance.

In common with many of your readers among the miners, I hope that you will agitate the question for the formation of a National Department of Mines and Mining.

ANDREW G. MYERS.

Fort Jones, Cal., March 5, 1894.

Great Mines of California.

Conclusion of Melville Attwood's paper on "Metalliferous Deposits," read before the Academy of Sciences March 5, 1894.

The gold mining business in California has seldom looked brighter than at the present time. Old abandoned mines are now being opened out and worked with success; water, improved methods of extracting and milling the rocks, cheap labor and reduced cost of supplies enabling the miner to work rock to a profit for what it cost him to mill it in the early days.

I feel confident that if the same amount of capital now being spent in the African gold mines were judiciously invested in our California gold mines, the results would be so satisfactory as to again attract miners from all parts of the world. One instance of the results of judicious investment of capital in California was the Eureka mine. The enterprising Jules Fricot purchased it, and in 1864 sunk a perpendicular shaft to the depth of upward of 100 feet, which intersected the pay shoot at that depth. He then built a quartz-mill and erected hoisting and pumping machinery. He afterward disposed of part of the property to a San Francisco company, who took out \$5,700,000 from the claim, a large proportion of which was paid in dividends. The Idaho and Maryland claims are a continuation of the Eureka pay shoot, and in the same fissure. The Coleman Bros., to whom Grass Valley is so greatly indebted, first bought the abandoned North Star mine, made a success of it, and then sold it for a large sum of money. They then commenced work on the Idaho, which, by good management, has proved so far to be the richest mine in California, yielding in the neighborhood of \$12,000,000, and it is said, nearly one-half of that has been paid in dividends. No mining capitalist on this coast has developed richer gold mines than Alvinza Hayward Esq., and his operations have not been confined to a few localities. With good judgment and practical knowledge he has opened out old abandoned mines, and, with the aid of improved machinery, made them good paying concerns. For instance, the Utica mine, the output of which for a considerable time has been greater than the richest of the African gold mines.

By the action of the directors at Sacramento, Denver Waggoner has been appointed to succeed Stephen B. Fowler as superintendent of the Granite Hill mine, Nevada county. Within a few weeks work will be resumed.

CONTRARY to the expectations of many, the Bland seigniorage bill has passed the House. It appears to have an even chance of passing the Senate.

The Gold Mines of Plumas.

J. A. Edman in *Plumas National-Bulletin*.

Foremost among the resources of Plumas county stand its mines of gold, silver, copper and iron, of which the gold mines alone have as yet received any extended development, considering the extent of the county. Occupying an area of 2600 square miles, or more than the whole of the State of Delaware, and with a population of less than 5000, it could not be expected that even the ubiquitous prospector had explored all of its rugged and remote fastnesses. As a consequence the principal mines are found near the highways traversing the county.

The main gold-bearing belt of California, which in the middle counties is comparatively narrow, and in Amador and Nevada counties seldom exceeds 30 miles in width, gradually widens in following the trend of the Sierra Nevada northwesterly, and in Yuba county attains a breadth of about 42 miles. Expanding still farther, we find it in the region opposite Oroville covering an area over 70 miles wide, measured on a line running northeast from Oroville and through Butte and Plumas counties. Gradually curving westward it maintains and even exceeds this

where the Sierra Nevada may be traced as one continuous chain, with the affluents of the Sacramento and San Joaquin rivers coursing down its western slope, and generally at right angles with the trend of the mountain chain, a break in the system occurs in Sierra county, and within Plumas appear two well-defined ranges, of which the western presents two separate axes of uplift, marked by peaks rising to 7000 feet altitude. The eastern range, forming the watershed between the Pacific and the Great Basin, is distinct and well defined from Summit peak northward, but before it approaches Lassen peak, merges into and intimately connects with the main mass of the Sierra.

The drainage system of Feather river and its tributaries which ramify through every part of the territory, presents peculiar features. The North Fork, rising well toward the summit of the eastern range, in the region of Mt. Lassen, pursues a general north and south course, cutting a deep gorge in the western range. The Middle Fork, rising in the elevated valleys between the two ranges, takes first a northwesterly course, then breaking through both divisions of the western range, eroding its bed over 3000 feet deep, turns westward, then southerly, and unites with the North

of Nevada and El Dorado counties, that the mines of the western division produce most of the free-milling quartz, as well as ores associated with iron pyrites alone, while the veins of the eastern division furnish some refractory ores, associated with copper, galena, zinc-blende and arsenical pyrite. The eastern range of the Sierra is here eminently the copper-bearing region, and, at its junction with the main range, as at Genesee valley and Lights canyon, free-milling gold ores are found side by side with large and important copper lodes, as well as, but rarely, with silver-bearing veins.[†]

The more important ore deposits of Plumas county may, for purposes of description, be placed in the following ten groups, each group chiefly determined by distinctive rock formations and to less extent by topography:

- | | |
|-------------------------|---------------------|
| 1. Granite Basin group. | 6. Genesee group. |
| 2. Spanish peak " | 7. Lights canyon " |
| 3. Diadem " | 8. Plumas-Eureka " |
| 4. Black Hawk " | 9. Pilot peak " |
| 5. Indian valley " | 10. Feather river " |

[†] The systematic geology of the Sierra Nevada, both outside of and within Plumas county, has been scientifically investigated by Prof. James E. Mills of Quincy, but only a small part of his deductions

THE SAN JOAQUIN COUNTY BUILDING AT THE MIDWINTER FAIR.

width, till in the vicinity of Big Meadows the volcanic formations centering at Lassen's peak encroach upon and cover its northern portion, while the main gold-bearing belt continues into Shasta and Trinity counties.

Situated entirely within the high Sierra and generally above an altitude of 3500 feet, the western border of Plumas attains an elevation of nearly 4000 feet, except in the gorges of the North Fork and Middle Fork of Feather river, where erosion has cut its bed to less than 2000 feet above sea level. Its northern and eastern border from Mt. Harkness (altitude 8875 feet) to Summit peak (8302 feet) in the south, follows the crest of the easterly range of the Sierra Nevada, the watershed between the Pacific and the Great Interior Basin, and with an average altitude exceeding 6000 feet, except where cut by the natural gateway to California at Beckworth's Pass, at 5220 feet elevation.

With the exception of about 360 square miles of northern Plumas, covered by the geologically recent volcanic deposits radiating from Mount Lassen, and the elevated basin of Sierra valley in the south occupying nearly 200 square miles, the whole of Plumas county presents several systems of metalliferous veins and lodes, as well as an infinite variety of recent and ancient gravel deposits, which attain their greatest extent and importance within the southern and western sections of the county.

As far as they are intimately connected with the origin and distribution of its ore deposits, the topography and stratigraphy of this mining region may here be briefly reviewed.* Unlike the counties to the south of Plumas,

Fork in the foothills of Butte county.

The magnificent water power that these streams furnish and the facilities for thorough drainage in mining operations which the deep canyons afford, have been as yet but slightly appreciated and still less utilized for economic purposes.

The largest portion of the eastern range of the Sierra belongs, in climate, in natural history, and in geological features, to the Great Basin. Its lithology has been but little studied, and its mineral resources scarcely at all developed. Where it merges into the western range, its stratigraphy has been well investigated by J. S. Diller of the U. S. Geological Survey, and its ore deposits have there been fairly well developed in the gold and copper mines near Genesee valley.

But it is within the western range that the gold-bearing rocks attain their greatest development in Plumas county, and within this area, comprising fully 1800 square miles, not a township is to be found, where exploration has failed to show valuable lode or gravel deposits. In viewing the rock formations, a distinction may be made between the eastern and western divisions of the west range, as, while both contain crystalline, archaic and metamorphic rocks, the eastern division, in which Eureka peak, Argentine rock and Mt. Hough mark the summit of elevation, presents a great variety of volcanic and trap rocks, such as tufas, basalts, trachytes and porphyries; while the western division, having as its monuments of uplift Pilot peak, Claremont and Spanish peak, is chiefly represented by granites, syenites and metamorphic slates. In relation to character of ore deposits, a generalization may be admissible, conforming to the evidence of the gold-bearing lodes

has been published, mainly in the bulletins of the Geological Society of America.

San Joaquin County at the Fair.

The county buildings comprise some of the most unique and attractive features of the Midwinter Fair outfit, and the county exhibits are the backbone of its industrial display so far as natural resources are concerned. Without these factors the Midwinter Fair would fall far short of its present standing as an exponent of California progress and achievement. Due credit should therefore be given to county enterprise and to the individual efforts which made the aggregate possible.

We give on this page a view of one of the most notable of the county structures, that of San Joaquin county. San Joaquin has a good record for enterprise in industrial displays. Its Midwinter display is the greatest of all its achievements, and one which shows best its various means of wealth creating, for it bespeaks in its entirety the enterprise and generosity of the people, and in its materials displays the achievements of the manufacturing interests of a thriving city as well as the productions of rich fields, orchards and gardens. One can hardly contemplate the exhibitions made at the fair without feeling the conviction that some of our counties are fitted to rank as States or empires upon the basis of natural and developed wealth and successful industry.

The engraving shows so well the style of the San Joaquin building that little description is necessary. It is of commanding dimensions and fitting style. Its interior is excellently adapted for the purposes in view, and affords not only opportunity to display but opportunity to see and

*The general geography and topography of Plumas county has been ably determined and illustrated by the surveys and maps of A. W. Keddie, C. E.

to obtain both near and distant views, and to rest during contemplation. Its cupola also affords a good lookout over the fair site which is much enjoyed. The building was put through in an almost incredibly short time, and speaks well for the energy and sagacity of Mr. P. A. Buell of Stockton, to whom the management of the whole enterprise was entrusted.

The Water Supplies in the Arid Regions.

Part III.

By J. W. Powell, Director of the U. S. Geological Survey.

Sources of Water Supply, Continued.

[Major Powell uses a specially prepared map to show estimated runoffs from the different regions of the United States, and continues as follows:]

In the construction of the runoff map the laws heretofore explained have been used, and topographic features have received consideration. It will be seen that the runoff map does not wholly coincide with the rainfall map, from the fact that topographic features play a more important part in runoff. Altitude affects rainfall, and altitude and character of surface affect runoff; and as rainfall becomes less, runoff is affected by character of surface in a steadily increasing ratio.

Turning to the districts represented in the map, the following statements may be made: It has been seen that the practical duty of water is 24 inches. Now, where the runoff is from 5 to 10 inches, if all the runoff were caught and used in irrigation, nearly one-third of the land could be irrigated, but in that region the rainfall itself is usually sufficient for agriculture, and irrigation is only needed as supplementary to the rainfall.

Effect of Topography.—Where the runoff is from two to five inches the total is about one-seventh of the amount necessary for irrigation; that is, a catchment of seven acres, if all is utilized, will irrigate one acre. Where the runoff is from nothing to two inches some interesting conditions are found, which must be more fully explained. Here the topographic conditions are controlling, and very large districts exist where there is no runoff, and other districts where the runoff is very slight, it being found only in storm-water streams and very infrequent springs. We may divide this district where the runoff is from nothing to two inches into three portions, which appear to be nearly equal. As determined by topographic conditions and diminished rainfall, one-third will have no runoff, another third will have a runoff of one inch, and the remaining third a runoff of two inches. If all this water could be caught and used upon the land in irrigation, then on the land where there is no runoff there would be no irrigation; on the second portion, where the runoff is one inch, one acre in twenty-four could be irrigated; on the third portion, where the runoff is two inches, one acre in twelve could be irrigated.

Absolute Catch and Possible Catch.—So far we have considered the problem only on the supposition that all of the water can be caught, but this is not possible. The total runoff we will call the absolute catch, and we will now proceed to find the possible catch, the practical catch and the crude catch, as we have defined the absolute duty, the possible duty, the practical duty and the injurious duty of water.

The water which is used in irrigation must be caught. The season of irrigation is short as compared with the remainder of the year. All the water which is not used as it is caught must be stored in reservoirs; but from these reservoirs a part of the stored water will evaporate, the amount varying in different latitudes and altitudes from 50 to 100 inches annually. That is, if a reservoir has a surface of 10 acres, then 10 acres of water 50 to 100 inches in depth will be evaporated annually. It is not possible, therefore, to hold all the water stored; but if we suppose that the catch of the waters be perfect, which can be effected only at an enormous and impracticable expense, then the possible catch is that which is used immediately after being caught and that remaining in the reservoir after evaporation. This possible catch will be 30 per cent less than the absolute catch. Space does not here permit of a discussion of the facts which lead to this conclusion, and only the simple statement is made. The possible catch, then, is 70 per cent of the absolute catch.

The Practical Catch.—The possible catch is impracticable by reason of excessive cost; and we have a further reduction to make. Where the catch is concentrated by greater rainfall and most favorable conditions of topography, the practical catch is comparatively large; where the rainfall is less and the topographic features more unfavorable, the practical catch is very small. It will never pay to impound the storm waters of sand deserts; it will never pay to impound the storm waters of bad lands; it will never pay to impound the storm waters of land of volcanic scoria; and there are many other minor conditions of

storm-water catching which are inhibitory. Storm waters can rarely be caught at a practical expense where the rainfall is less than 12 or 15 inches. All such waters must therefore be neglected as not entering into the problem of the catch. But where there are mountain lands which condense an amount of water greater than the adjacent lowlands, and where at the same time the catchment surfaces are topographically advantageous, very large quantities of storm waters may be secured; but to a large extent they are added to perennial streams, and their catch, therefore, depends upon the control of perennial streams.

Limitations upon Cultivation.—There is still another important factor to examine in this connection. Rains fall in intermittent storms. Some showers are gentle and furnish small amounts of water; some great storms furnish large quantities of water. The maximum storms which cause destructive floods fall at intervals of years. Now it will never be practicable to catch all the water of maximum storms, because of the great expense of constructing the necessary works. On every stream where works are constructed for diverting the water, spill-ways are necessary to provide against the maximum storms. Practically, it will be found economic to waste all the water of storms which much exceed the mean, and these are the rains which serve greatly to increase the runoff.

We have, then, to deduct from the possible catch that portion of the storm-water streams which must be neglected and that portion of the great storm floods which will be spilled, which together amount to about 30 per cent. Thus the possible catch will be reduced to the practical catch. The reason for reaching this conclusion cannot be entered upon here for want of space. It is thus found that there are inexorable conditions which limit the amount of land which can be practically cultivated in the arid region. The practical catch and the practical duty of water set these limits.

How Mountains Effect Rainfall.—Before proceeding to apply these laws in estimating the amount of land which can be irrigated, another important fact with regard to the water supply should be pointed out. Mountains concentrate the rainfall. Thus, in the great system of the Park mountains of Colorado; in the Wasatch and Uinta mountains of Utah and Colorado; in the Black Hills and the geyser mountains of Wyoming, stretching up into Montana; and in the great mountain systems of Montana and Idaho, large areas of increased rainfall are found. Again, in central Washington, Oregon and eastern California, the Cascade mountains and Sierra Nevada furnish another example of increased rainfall. This gives to the arid lands of these States, where irrigation is necessary, large streams of water having their sources in the mountains where the rainfall is great and the runoff is also great. In the upper regions little or no irrigation is necessary, and only small areas can be cultivated because of the mountainous character of the country. These mountain-born waters, therefore, may be used upon the mesas, plains and valleys below. This gives to all of these districts a large source of water supply, which is often limited only by the distance to which it can be practically carried in canals. In making a general statement of the amount of land which can be irrigated in the United States, it is necessary to consider these facts also.

Amount of Land that Can Be Irrigated.—It is proposed now to consider those areas of country in the western half of the United States where the rainfall is 20 inches or less. There are large districts of country which can be profitably irrigated where the rainfall is more than 20 inches, but for present purposes these are neglected.

The total area where the mean annual rainfall does not exceed 20 inches is about 750,000,000 acres. The water to be used in irrigation in all of this country, with some slight exceptions hereafter to be noted, is the natural runoff from the same areas, to which must be added the amount of water caught in the mountain regions where the rainfall is more than 20 inches, but which runs down where it can be taken upon the lands having 20 inches of rainfall or less. When we compute the absolute runoff of all of this region, it is found that if it could be all caught and all distributed upon irrigable lands at the rate of 24 acre-inches to every acre of crop, the amount which could thus be irrigated would be about one-tenth of the whole, or 75,000,000 acres. But this supposes an absolute catch, which is impossible. Reduced to the possible catch (which is not practical) the amount is little over 52,000,000 acres. This reduced again to the practical catch gives a little over 36,500,000 acres. This, then, is the amount of land in the arid region where the rainfall is 20 inches or less which can, under practical conditions, be redeemed for agriculture by irrigation through the use of the natural runoff. But to redeem it, all the practical catch from the arid region and from the mountains which deliver their water into the arid region must be utilized.

In the above estimate only natural runoff has been con-

sidered. We must now turn attention to other sources of water to which reference has been made from time to time.

It will be seen that in making this estimate it is proposed to transform runoff water into flyoff water through the agency of growing crops and the evaporation consequent on the processes of irrigation. Now a portion of the natural flyoff can be caught before it is evaporated and can be used in irrigation.

Supplies by Pumping.—First. Some of the rainfall sinks away into the earth, where it in part runs off by spring, but in chief part by slow evaporation, coming to the surface by slow evaporation, coming to the surface by capillary attraction. This water which sinks into the soil can be utilized as an important supply, adding to the total only a small percentage, it is true, but when measured in acres the amount is worthy of consideration. Into the surface soils and rocks wells may be sunk and the water may be pumped upon the land for irrigation. The actual experience of mankind throughout the world exhibits the fact that millions of acres are thus cultivated. The tracts redeemed by single wells may be small, but such pump wells in the aggregate furnish considerable quantities of water, even in measures which irrigation requires, by acre-inches and acre-feet.

Artesian Waters.—Second. Waters which sink away underground are often carried to considerable depth, and may be returned to the surface by hydraulic pressure under proper geological conditions. These supplies are known as artesian waters. In the practical operations of irrigation throughout the world, it is found that artesian wells may be made to supply considerable quantities of water for irrigation. Single artesian wells furnish on the average much greater quantities than single pump wells; but artesian wells are successful only under greater intervals of areal space.

Floodplain Waters.—Third. Along the course of storm-water and perennial streams there is usually found a floodplain—a belt of country on either side of the stream which receives the overflow from the stream when great storms occur that swell it beyond the capacity of its banks. In such floodplains accumulations of sand and gravel are found irregularly distributed among soils and clays. These sand and gravel deposits become natural reservoirs for water, which comes down in part from the adjacent hills, but in larger part from the great floods. Now, these floodplain waters can be secured for irrigation, either by tapping them with canals that lead to lower ground, or by sinking wells and pumping out the water. In actual practice both the gravity method and the pump method are used, but in general the pump method is found more economical.

The irrigable area of the arid region can therefore be increased from these three sources, but the quantities cannot be exactly defined without most thorough geological research. Some districts will afford much, some little, by varying geological conditions, but actual experience proves that the amounts are considerable and worthy of notice in such an account of water supply as we are now giving. It seems probable from the general experience of other lands that three or three and a half million acres may be added to the total for the arid region by the use of pump waters, artesian waters and floodplain waters. This, then, will give to practical irrigation in the arid lands where 20 inches of rainfall or less is found, a total area of 40,000,000 acres.

Amount of Land Under Cultivation.—In no civilized land is all the land cultivated. Denmark has the greatest amount, where 75 per cent is under the plow. When these 40,000,000 acres are cultivated by methods of irrigation they will be found wonderfully productive, and their products will support a population as great as that found in the United States at the present time. It must be many decades before it is all redeemed. As from district to district farmers come nearer to the realization of the practical catch, more refined methods of catch will be adopted and the practical catch will be increased; but this will not result in increasing the acreage cultivated, for, at the same time, better methods of irrigation will be developed, from which a greater production will result and which will require a greater practical duty of water.

A word must be said about the character of this investigation and the degree of probability which inheres in its results.

In measuring rainfall and runoff, only averages can be given. A farmer sells a field of corn standing in the shock. In order that he may establish its value, he husks and measures a few shocks and derives therefrom an average which controls the quantity in the terms of the sale. The average thus obtained will never, except by accident, be exactly that of any one shock of corn, and yet an approximation to accuracy will be reached sufficient for practical purposes of trade. In like manner, the statements made in this paper are rarely, if ever, absolutely accurate for any one small district of country, and the quantities must al-

ways be taken as mean quantities, which only approximate accuracy.

Most of the lands now irrigated are watered by streams and irrigating works that do not require the most expensive plants; that is, the small streams are nearly all taken out upon the land, and a small stream irrigates a small area at a correspondingly small total cost. As irrigation is extended, larger and still larger plants are generally, though not always, necessary, and for this purpose aggregated capital is necessary. This capital will sometimes be secured by co-operation among the irrigators themselves, and sometimes capital will itself lead the way, for the purpose of increasing the value of lands and selling the same with water-rights to the farmers. Whatever method is pursued, aggregated capital must be employed. Therefore the farmer and the capitalist alike are interested in these results. Before money or labor is to be invested in irrigating works, it becomes necessary to consider the water supply. Is there land? is the first question raised; Is there water? is the next question; and, Can the water be carried to the land with reasonable economy? is the third. Many canals have been constructed without a proper consideration of these three questions, and already capital has been wasted, and we have now reached a time in arid America when these three primary questions relating to irrigation enterprises should be properly answered, before lands are bought and sold, homes established, labor organized and capital invested. Without these precautions bonds are worthless.

The Red Point Drift Gravel Mine.*

By C. F. Hoffmann, Mem. Tech. Soc'y.

In Three Parts.—Part I.

In starting the work of this mine the writer could find no published data upon which to base any estimates, and concluded to keep a full record during the progress of the work for future use.

The Red Point is a drift mine in one of the ancient lava-capped river channels of the Forest Hill Divide, Placer county, California, located at an elevation of 3875 feet above sea level, or 2000 feet above the North Fork of the American river. It belongs to the Golden River Mining Co. of Paris. The channel is known as a "blue channel," from the color of the gravel.

Discovery.—This channel was first discovered in the Mountain Gate mine, at Damascus, about a mile and a quarter distant from Red Point. The Mountain Gate was originally located on a channel of white quartz gravel known as the "white channel," which the owners followed in a southerly direction into the hill for a distance of 6500 feet, where they found it sharply cut off by a flow of lava or volcanic cement. The words "lava" and "volcanic cement" are used as commonly applied by gravel miners. The material in this section is composed of consolidated sediments from a volcanic mud flow, which have been variously described as tufts, tufas, breccias, conglomerates and cements. There is little or no evidence of a molten lava flow in this section except perhaps on the summit, where the lava is crystalline. The bedrock, with the volcanic cement resting upon it, pitched sharply to the south. After drifting to and fro along the contact, hoping to find the continuation of the white channel, the bedrock was followed down on its pitch, and the gold found to continue as far as the exploration extended. A drift was then run into the volcanic cement, and a winze sunk 90 feet down to bedrock, disclosing what is known as the blue channel. This channel was worked up and down stream for 1400 feet of its length, establishing its approximate course as southwesterly, or nearly at right angles to the white channel. It had not only cut away a large section of the older channel, but had worn down its bed to 90 feet greater depth. Soon after this the extension of the white channel was discovered on the opposite hillside, several miles to the south, where the Hidden Treasure mine was located. From this point of discovery it was followed up stream into the hill to the north for a distance of 10,000 feet. Here again it was cut off by the same lava flow covering the blue channel. It is this blue channel that the Red Point mine is located upon.

The Gold River Mining Co., having secured the ground to the northeast, had careful surveys made of the Mountain Gate mine and also of the rimrock (contact between the volcanic cement and bedrock) exposed on the surface for a distance of 8 or 9 miles to the northeast, along the Forest Hill Divide. These surveys, including levels, furnished an assurance of the confinement of the channel within the company's ground. There were no points of the rimrock low enough to permit of the escape of the channel; it was virtually hedged in. Upon the basis of these surveys a

point was located, and the Red Point tunnel started to tap the blue channel.

The data here presented concern this tunnel and the developments made through it. It was driven through slate bedrock in a southerly direction, the blue channel being tapped by means of an upraise 22 feet high, started at a point 1840 feet in the tunnel. The general features of the Forest Hill Divide are described in the State Mineralogist's report of 1890, and the map accompanying that report is partly based on the surveys made for the purpose just described.

Appended to this paper is a reduced copy of a portion of the above map, which will show the location of the Mountain Gate and Hidden Treasure developments in the white and blue channels, and the work of the Golden River Mining Co., from the Red Point tunnel.

The Tunnel.—The tunnel is 7x8 feet in the clear, has a grade of 3 inches in 100 feet, and when originally run had a double track for the first 100 feet, with a drain ditch in the center, and from that point on, a single track with the drain ditch on one side, and switches every 500 feet. The switches and double track have since been removed, as there was no further use for them.

The rails used are 16-pound steel rails, with a gauge of track of 20 inches. The air compressor is located 200 feet vertically above, and about 300 feet distant from the mouth of the tunnel, the air being conveyed through a 3-inch pipe which, in the tunnel, has valves and blowouts every 500 feet for the purpose of ventilation. There were no other pipes in the tunnel, except a 1-inch water pipe for drilling use (as at the time of running the tunnel).

After the location of the tunnel it was necessary to build a wagon road 6500 feet in length, leading from the summit to the compressor site, a difference in level of about 700 feet, also to bring water a distance of 2800 feet in a 2-inch pipe, to supply the works. The steepness of the canyon in which the tunnel is located made it necessary to do a great deal of grading, and to build crib work to make room for a framing yard, blacksmith's shop, etc., the cost of which is given further on, under the heading of "Yards, Dumps and Trails."

Work on the tunnel proper commenced on the second day of July, 1886, and 108 feet were run by hand with an average force of 6 men per day. The compressor was started on the fifth day of August, and on the 31st of January, 1887, the tunnel had reached a length of 1552 feet. The last 1444 feet were run with an average force of 20½ men per day. During the seven months the compressor was idle for 15½ days, on account of an accident to the air valves and the cracking of a casting, maklog li, therefore, only 6½ months work on the 1552 feet, or an average of 234.1 feet per month, including the hand work. The two largest runs made for two consecutive weeks were 71 feet for the week ending August 28th (six days work), and 84 feet for the week ending September 4th, or respectively 11.82 and 12 feet per day. The tunnel runs diagonally across the strike of the rock, which consists of strata of metamorphic slate, alternating with sheets of diabase, diorite and barren white quartz.

The regular force of men employed (when full) consisted of

15 miners working.....	8 hours per day.
2 engineers working.....	12 " " "
2 drivers working.....	12 " " "
2 blacksmiths working.....	10 " " "
1 timberman working.....	10 " " "

divided into three shifts and working two air drills on columns. The blacksmiths and timberman only worked in daytime, unless on account of hard rock, it was necessary for the blacksmiths to work extra time.

COST OF SURFACE IMPROVEMENTS, PLANT AND TUNNEL.

	Total Cost.
Road.—6,500 feet long; average grade 1 foot in 10 feet; commenced May 26, 1886; completed July 1, 1886. Average force of men per day, 9.2; cost including surveys and powder.....	\$ 963.00
Yards, Dump and Trail.—Commenced June 21, completed July 31st. Average force of men, 5.6; cost including crib work, timber and powder.....	508.05
Boarding house, office, blacksmith shop, stable, powder house, wood shed, framing sheds, snow sheds, etc....	2,310.10
Water Works.—Log Dam, 2-inch pipe, line 2,800 feet long to ditch and covered; commenced May 30th and completed July 30th. Average force of men per day, 2.74. Cost, including surveys, powder and pipe.....	604.94
Air Compressor.—Erection commenced July 1st; completed with pipe line to tunnel July 30th. Average force of men per day, 5. Cost of labor.....	970.00
One No. 44 Ingersoll straight-line compressor, 16 x 16 x 24; one 54" x 16' steel hoiler, complete; air tank, pump, three 3½-inch Eclipse drills and extras, freight and building 30 x 40 feet.....	7,819.86
Eight iron cars.....	1,200.00
Two tunnel horses, two team horses and huckboard.....	705.00
Total cost of plant.....	\$15,080.95

ACTUAL COST OF 1552 FEET OF TUNNEL, 7 X 8 FEET, UP TO FEBRUARY 1, 1887, EXCLUSIVE OF MANAGEMENT, INCLUDING 43 TIMBER SETS.

	Total Cost.	Cost per Running Foot.
Total labor (pay roll).....	\$11,418.47	\$ 7.56
Powder.—10,567 pounds Giauot No. 2, and 325 pounds No. 1, at 26½ c., 41½ c., 10 per cent off.....	2,641.64	1.70
Fuse.—39,650 feet at \$5.50 per M., and caps \$45.....	263.07	0.17
Wood.—402 cords at \$2.75 delivered.....	1,105.50	0.71
Charcoal.—1,604 bushels at 20c., delivered.....	320.80	0.21
Caolides.—1,760 pounds at 16½ c., delivered.....	290.40	0.19
Foot plank and ties.—7,355 feet of lumber at \$20 per M., delivered.....	147.10	0.09
Timbers.—43 sets at 6c. per running foot, delivered.....	46.76	0.03
Steel Rails.—16,640 pounds at \$50 per ton.....	510.00	0.33
Air and Water Pipes.—3 and 1 inch at 18c. and 5½ c. per foot.....	521.86	0.35
Horse feed.....	281.25	0.18
Material.—Steel, oil, tools, etc.....	693.00	0.45
Freights, at \$1.25 per 100 pounds.....	1,000.00	0.64
	\$19,239.85	\$12.40

With present reduced prices of powder, candles, etc., such a tunnel could now be run for \$11.25 or less per running foot.

From the upraise, 1840 feet in the tunnel, the channel was worked for a distance of 500 feet down stream to the west, and for a much greater distance up stream to the east. A branch tunnel was run at the same time under the easterly extension for a distance of 1300 feet, and two upraises made into the channel to be used as gravel chutes. The second of these is 3040 feet from the mouth of the tunnel.

This point reached, it was apparent that the gravel was not rich enough to warrant the extra expense of a bedrock tunnel and upraises. A slope was therefore raised from the end of the branch tunnel into the channel with a grade of 1 foot in 2½ to serve as a footway for horses. The upstream work in the channel was then continued as before, but without a tunnel underneath.

The Channel.—The gravel occupies a typical river-bed, with all its windings, bars, islands, pot holes, branches, etc., which only differs from the present rivers in its volcanic cement capping and somewhat greater grade. Its general course is southwesterly. It has a uniform grade of about 70 feet to the mile. Its bottom width is from 75 to 650 feet; average 200 feet. There have been encountered several islands, reaching heights of 12 or 14 feet above the average bed, and three large pot holes 80 to 120 feet long and 50 feet wide and 9 to 14 feet deep. As a rule, such holes are filled with large boulders and sand, and contain no gold; but in this case two of them contained rich gravel—one in its southerly half, the other in its northerly quarter, and the third was entirely barren. These holes were all found in hard bedrock. The soft rock is generally more uniformly graded, and has a level surface. Large trees, pines and cedars, almost unaltered, are of common occurrence in the volcanic cement immediately overlying the gravel, and this fact proves that this material was delivered in the form of a mud, and not as molten lava. Pine cones (apparently *Pinus Contorta*) and small branches have been found in the gravel. No fossil bones of any kind have so far been discovered.

The Bedrock.—The bedrock is principally metamorphic slate, often carrying large crystals of iron pyrites, and interstratified with calcareous schists, sheets of diabase and diorite and quartz veins. The general strike of the strata varies from N. 25° to 32° W., and the dip from 45° to 80° to the northeast.

The Gravel.—The gravel consists of boulders, principally of metamorphic schists and porphyrites with a very small percentage of quartz, intermixed with small pebbles and sand, and occasionally fine particles of iron pyrites. In some places the gravel of the old water courses is loose, with very little fine material between the boulders, and the latter are often covered with iron pyrites. As a rule, the gravel in the mine has a bluish color, which gave rise to the name of "blue channel;" but there are places where it is nearly black or red, and evidently discolored by percolating waters. When delivered to the surface and dried, it has more of a grayish color. The gravel is "free"—that is, it is soft enough to be washed without crushing, although blasting is resorted to as a means of facilitating extraction. The depth of the gravel is from a few inches to 16 feet, generally seven or eight feet in the center of the channel, thinning out to a mere seam on the rims. It is immediately capped with the volcanic cement, which forms a fine roof to work to. The overlying cement has a depth of 500 to 1000 feet, and is in the form of beds with intervening layers of gravel. The latter sometimes are also gold-bearing. The washed and rounded boulders are often two or three feet, and occasionally six or eight feet in diameter.

*The accompanying paper, of which an abstract was printed in the PRESS on Jan. 13, 1894, is a most important contribution to literature on the subject of drift mining. In response to numerous inquiries, and by permission of the Technical Society of the Pacific Coast (before which the paper was read), the full text is given.

Scientific Progress.

The Solar Corona.

Professor Schaeberle, of Lick Observatory fame, lectured at the University of California last week. "On account of the scope of the subject," said the astronomer, "I will have to limit myself to the corona of the sun. Before entering upon that, however, it will be necessary, to make my succeeding remarks intelligible, to review in a brief outline the principal points concerning the present knowledge of matter in space."

The lecturer then referred to the state of matter existing in the solar system, and gave in brief the present theory of the evolution of the system. The law of mechanics, that any contracting body of space will attain a rotary motion, was especially emphasized; also another definite law, that the angular velocity of rotation increases as a body contracts.

Then there appeared upon the screen a number of photographs and drawings of the sun, showing the spots, the protuberances and the coronal light. Many of these were from the Lick, others from the Harvard Observatory, and one from the University of Chicago.

"Formerly the corona could be seen and photographed only during a complete eclipse, but now, by an ingenious device, photographs showing the coronal streamers can be taken any time," said the lecturer. "These flames dart out sometimes 200 miles in one second. This motion can be seen frequently by the observer."

The speaker pointed out on all of the views of the sun's disc the excess of matter near the equatorial region, forming two indistinct bands surrounding the spheroid mass and at about 15 degrees latitude on each side of the equator. The excess of matter in the vicinity of the equatorial region is always to be observed of the corona.

About four years ago the mechanical theory of the corona and the spots was promulgated. This is, in substance, that all matter that goes to make up the luminous corona comes from the interior of the body toward the surface, according to well-known mechanical laws. This theory was hit upon by constructing a model of the sun and reproducing the conditions conceived as existing therein.

Professor Schaeberle then narrated in some detail the difficulties in the way of a successful trip to Chile one year ago.

"My trip to South America," said the lecturer, "was for the purpose of photographing the sun's disc to show the corona. I resolved to perfect some arrangement by which I could procure larger images. This was done by the aid of an improvised telescope, and the resulting views show coronal streamers, a phenomenon never before photographed."

"At this point I must speak of a theory of the coronal light, which has occupied considerable attention from astronomers—the magnetic theory. This explains the curves of the corona by supposing them to be due to magnetic forces organized about magnetic poles of the sun. The falsity of this theory is demonstrated by several of the photographs obtained in the Andes."

"Whatever theory is put forth to explain the sun spots and coronal border must rest upon laws of mechanics, and upon the further fact that the body in question is a rotating, incandescent liquid or gaseous sphere. Such a body is cooler on the surface than at the interior; hence it would have circulating currents from the interior to the surface. Now, if the body rotates also, then the currents moving outward would be deflected toward the equator with a gradual but continuous speed. Thus an equatorial band of gaseous or liquid matter will accumulate with two weak spots on each side of the equator. The continual

rotation of the body will cause these weak and strong spots to change relative positions constantly, and this explains entirely the periodicity of the sun eruptions causing the coronal streamers. This condition of things must obtain in every rotating, incandescent, gaseous or liquid spheroid, whether sun or some other body."

Attempts at Cloud Photography.

Good photographs of clouds, especially of the delicate white plumes of cirrus, would be of great use in certain lines of meteorological study, apart from their artistic value. It has been hard to secure such pictures, however, owing to the fact that the blue sky has the same actinic effect upon an ordinary plate that the white vaporous masses produce, so that no such contrast is obtained photographically as is apparent to the eye. Various means resorted to, in order to obviate this trouble, were recently discussed in *La Nature* by M. A. Angot, his essay having been originally presented to the Paris Physical Society.

One fairly successful plan is to ascend a mountain, where, owing to the greater purity of the air, the sky forms a darker background than at lower levels. This is an expedient not in every one's reach, however. Prof. Riggenbach uses a diaphragm with a very small perforation in front of his lens, and makes a short exposure. This gives only a faint image at first, but a perceptible contrast; and then the process known to photographers as "intensification" is resorted to. But there is danger of ruining plates by this operation. Another method tried by the same expert was to polarize with a Nicol prism the light entering the camera. Only a part of the rays proceeding from the sky would then get access to the plate, while the light from the clouds would remain unaltered.

A plan employed by M. Angot himself takes advantage of the fact that the clouds are rather rich in yellow and green rays. He places a "color screen" before his lens that will readily transmit such rays, but exclude blue and violet. This is attended with excellent results when the clouds are stationary. As yellow and green light is very slow in its action, prolonged exposure is required; and if the clouds be pure cirri, or cirro-cumuli, a little movement will impair the sharpness of their detail and make a sad blur. In this work, M. Angot prefers a liquid screen. An almost saturated solution of bichromate of potash, to which a few drops of hydrochloric or sulphuric acid have been added, or saturated solutions of bichromate of potash and sulphate of copper in the proportion of three of the former to one of the latter, may be used, between glass plates having parallel surfaces, and about five or six millimetres apart.

The Planet Jupiter.

Prof. E. E. Barnard lectured recently in Pioneer hall, S. F., under the auspices of the California Pioneer Society, on "The Planet Jupiter and His Satellite System." He described the peculiar features of the planet as seen through the telescope. Its surface is in variable condition and is changing constantly. When seen through the telescope it is a disk about as large as the thumbnail.

After detailing the belt markings and the spots on the northern and southern hemispheres, he described the large red spot which in 1878 appeared south of the great equatorial belt, elliptical in form and sharply defined. Ordinary markings on Jupiter are transient, but this red spot was the most prominent object on the planet for three or four years. It was about 8000 miles wide and 30,000 miles long, its area being equal to the surface of the earth.

Science has not learned what this spot was. The accepted theory is that the planet of Jupiter is a hot body—not heated to the

point of incandescence, but warm enough to convert all the water on its surface into vapor, which fills the atmosphere with a dense strata of cloud surface. This is changing all the time. The presence of the red spot was perhaps due to some sort of an eruption, which dissipated the clouds; that is to say, made a hole through them, and the spot was the visible surface of the planet not obscured by the steam.

In the equatorial belt every object is moving. The cloud forms move from west to east around the planet, making the circuit in 45 days. Roughly estimated, their velocity is four miles a minute, four times as fast as a hurricane on earth. The greatest motion of the clouds is not on the equator belt, but in a very narrow zone in 21° north latitude.

The four bright satellites of Jupiter are in every respect similar to our moon, revolving around the planet just as the moon revolves around the earth, except that their velocity is greater. The closest makes the circuit in 42 hours, the most distant (1,600,000 miles) in 17 days, while our moon takes 27 days to get around the earth. The reason they move so rapidly is the greater attractive power of Jupiter. Its attraction on the first satellite is 300 times greater than that of the earth on the moon.

PIONEER REDUCTION CO.,

NEVADA CITY, CALIF.,

Will Erect Chlorination Works for Mining Companies on Contract or will erect same on our own account provided suitable arrangements can be made with mining companies regarding supply of ores or concentrates.

Mechanical Progress.

Harnessing the Ocean for Power.

A bold scheme for obtaining mechanical power for industrial purposes has lately attracted attention in England. It contemplates the construction of a dam fifteen miles long from the northeastern coast of Ireland across "North Channel" to the extremity of Cantire, Scotland, and putting in several gates and water-wheels, to be worked by the tide. Owing to the greater depth of the ocean than of the Irish Sea, and to the freer course afforded west and north of Ireland, the tide comes up from the South Atlantic by that route, and flows southward through the passage just mentioned long before it can get up there on the east side of the Green Isle. Moreover, the Gulf Stream, or rather the drift from it, bathes the northern part of Great Britain more freely than the southern, and a portion thereof is diverted southward by the Scottish coast, so as to make a continuous current, it is said, flowing down the North Channel. Here is a great deal of power going to waste, and it is not a senseless proceeding to consider the practicability of utilizing it somehow. American enterprise at Niagara has set the whole world thinking of such matters.

The depth of water, says W. Lodian in *The Electrical Engineer* (New-York), is 474 feet in mid-channel; but most of the way it is much less than this. The proposed "isthmus"—for that is what the engineers call it—would be about three hundred feet wide; and the material for it, it is thought, might be obtained from the high bluffs at the Irish end. The estimated cost is \$10,000,000; and the time named as necessary for construction is three years. Mr. Lodian neglects to say how much of head there is here; but the current flows at six miles an hour most of the way across, and at some places even faster. It is taken for granted that the power developed by this means would be converted into the form of electricity for transmission; but there is some question as to the localities in which it would be used. On the Irish side of the channel there are no large towns near at hand. Dublin is 126 miles away, and London 365; Glasgow, in a bee-line, is 75 miles distant, and Edinburgh about 50 more. Mr. Lodian thinks it would be more sensible to build this junction between Dover and Calais; for a viaduct as well as a dam is desirable at that point; and it is much nearer London. But such an obstruction in the English Channel, even with proper gates, would interfere with shipping.

Horse-Power.

Horse-power measures the rate at which work is done. One horse-power is reckoned as equivalent to raising 33,000 pounds one foot high per minute, or 550 pounds a second. In measuring the work of a horse the estimates of the most celebrated engineers differ widely from each other: Boulton and Watt, basing their calculations upon the work of London dray horses working eight hours a day, estimated it at 33,000 foot pounds per minute. D'Aubisson, taking the work done by horses in whips at Freiburg, estimated the work at 16,440 foot pounds working eight hours a day. Under similar circumstances Desaguliers' estimate was 44,000, Smeaton's 22,000, and Treadgold's 27,500 foot pounds. Horse-power is called nominal, indicated or actual. Nominal is used by manufacturers of steam engines to express the capacity of an engine, the element being confined to the dimensions of the steam cylinder, and a conventional pressure of steam and speed of piston. Indicated shows the full capacity of the cylinder in operation without deductions for friction, and actual marks its power as developed in operation involving elements of mean pressure upon the piston, its velocity, and a just deduction for the friction of the engine's operation.

The original estimate of Watt is still counted a horse-power. The general rule for calculating the horse-power of a steam engine is to multiply together the pressure in pounds on a square inch of the piston, the area of the piston in inches, the length of the stroke in feet and the number of strokes per minute. The result divided by 33,000 will give the horse-power.

Steel Boiler Tubes.

We must all admit that the use of the steel boiler tube is abreast with advanced scientific construction and experiment, says the *Boiler Maker*. The advocates of iron for boiler tubes have been very resolute and determined in their opposition to the introduction to use of steel, but practically the same opposition existed to the introduction of steel boiler plate when the latter began to supplant flange iron.

We heard the idea of using steel for boiler plate ridiculed on all sides, but flange iron has been laid on the shelf, and a specification for a steam boiler containing the words "flange iron" is of very rare occurrence. In this searching and crucial age the best survives, and steel boiler flues have come to stay. All acknowledge that there are poor steel tubes and poor iron tubes, but we claim superiority for the good steel article for many reasons.

They can be more evenly made. They can be welded more perfectly, and they are stronger and cheaper. More than this, the steel flue is rolled truer to gauge, and can be more easily placed in the boiler head. The well-worn argument against the steel flue, viz., that it pitted sooner under the action of water, has been contradicted by the best of authorities.

The New York Railroad Club discussed the subject thoroughly at their meeting last fall in the presence of some of the most noted representatives of iron and steel industries of England and Germany. The conclusion reached was that one material showed to better advantage in some waters, the other in other. This would seem to silence at least the general charge against the steel tube as regards pitting. As to the relative strength of steel and iron in boiler flues, it may be said that steel is almost always specified whenever a great strain is to be withstood, thus demonstrating a higher degree of tensile strength.

Paper Tires for Bicycles.

The pneumatic tire for bicycles is unquestionably one of the greatest improvements ever made in those vehicles. But its cost is a serious matter. Rubber is at present the only material in use for such tires. Leather has been tried, but it does not seem to give satisfaction. Paper, however, has recently been the subject of experiment for this purpose; and *The Paper Trade Journal* reports that success has been attained. In fact, it is asserted that two paper tires will, on the machine, cost only two-fifths or one-half what a pair of rubber tires cost; and, being less yielding, the new material may last much longer. Its champions claim that it will not be so easily cut or punctured by glass or sharp stones, and will not break from constant squeezing and inflation so soon as rubber.

Unfortunately, the names of the inventors are not supplied by our contemporary, nor is it at liberty to mention the ingredients incorporated with the pulp for such tires to impart toughness and elasticity. But *The Journal* adds these particulars: Drawing paper out into a tube is an art already known to manufacturers. The ends of a tube may be united by shaving off the inside of one and the outside of the other, and using a special elastic, watertight glue where one overlaps the other. The hair used in place of interior linings is forced into the hollow of the tube before the union is made. A special instrument is used so that the packing is uniform.

Any information mining men may desire to know, relative to the mineral or coal resources of the entire Pacific Northwest, will be honestly given.
DR. WILLIS E. EVERETTE, 1818 E. ST.,
Tacoma, State of Washington, U. S. A.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.
Price, \$6.00 post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Practical Hydraulics.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

By P. M. RANDALL.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulae, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is especially applicable to the Pacific Coast.

Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated:
General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulae Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formulae and Rules; Flow of Water through Openings; Weir Coefficients; Triangular Weirs; Flow of Water over Curved Weir (tabulated); Application of Tables; Submerged Orifices; Flow through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water through Short Tubes and Compound Tubes; Flow of Water through Pipes; Tables of Velocities and Cubic Feet Flows for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend, Circular Weir (tabulated); Flow through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.

Price, \$2.00, post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco, Cal.

Electricity.

Pending New Electrical Wonders.

In the new foreground, foretells E. J. Houston, I see a practical method for the production of electricity direct from the burning of coal. This achieved, there necessarily follows the universal adoption of the electric motor as a prime mover; the relegation of the steam engine to the scrap heap; and the almost immediate realization of the air-ship as a means of transportation.

Assuming the cause of chemical affinity to lie in the unlike electric charges of the combining atoms, I, continues this authority, see the practical realization of electric synthesis, whereby wholesome food products will be directly formed under the potency of electric affinities. I see, too, a marked advance in electro-therapeutics, whereby human life be prolonged and its sufferings alleviated. Diagnosis and prognosis will be profoundly aided by exact electrical measurements of the various organs of the human body as regards their electro-motive force and resistance. The electro-therapist of the future will employ electric charges and currents for restoring the normal charges and currents of the body, as well as for the stimulation of nervous or muscular tissues.

Back of these achievements I, adds Mr. Houston, discern a practical apparatus for seeing through a wire, that is, a device for looking into a receiver at one end of a metallic wire and seeing therein a faithful reproduction of whatever optical images are impressed on a transmitter at the other end, even though thousands of miles intervene. I see the possible use of the step-down transformer for the preparation of a road bed or road surface by the vitrification of clay or other suitable soil, by the intense heating power of enormous currents of electricity.

Electricity and High Temperatures.

A strong claim is now made that the application of electricity to the production of high temperatures has been developed to a remarkable degree by Henry S. O'Neill, of Boston, the result of whose recent researches, it is predicted, will create a great interest, at least among scientific men, says the *Chicago Journal of Commerce*. The furnace, which is 13x5x4½ inches in size, consists of three cylindrical shells, one within the other, with non-conducting walls and spaces between each. The inner wall is composed of diatomaceous or infusorial earth and asbestos porcelain bound together. Against this wall and between it and the one adjoining it, is an inch layer of infusorial earth. The next wall is of magnesite. Between this and the outer wall, which is composed of kaolin and fossil meal, is another layer of powdered calcined magnesite. In the furnace, with an outlay of energy not exceeding 2000 watts, a heat is said to be produced that readily vaporizes carbon, the critical temperature of which cannot be less than 6000 degrees Fahrenheit.

An Electric City.

Great Falls, Mont., appears fairly entitled to distinction of being called the Electric City. At Black Eagle Falls, three miles above the town, an immense dam has been thrown across the Missouri. Not only are the street cars propelled and lighted by electricity from the power houses, but they are heated as well by electric radiators placed in each car. Elevators, printing presses, cranes and all kinds of machinery are operated by the ubiquitous force. There are automatic excavators, electric pumps and electric rock-crushers. A not uncommon sight on the street is a mortar-mixer attached to an electric wire leading down from a pole. The restaurants cook by electricity, the butcher employs it to chop his sausages, the grocer to grind his coffee and the tailor to heat his goose. The subtle fluid is a

welcome blessing in every home; the housewives run their sewing machines and heat their flatirons by electricity; they have electric broilers and teakettles, and they bake their cakes in electric wooden ovens that can be set away on a shelves like paste-board boxes.

Heating Iron in Cold Water.

It would now seem as though the common, but time honored blacksmith's forge and all other kinds of fiery furnaces, will become extinct and live only in the memory of a rapidly receding past says the *Mechanical News*. The forge and furnace of the future will consist of a lead-lined glass or porcelain vase or cupola filled with cold acidified water, to which is connected a strong positive conductor. A pair of tongs with insulated handles attached to a flexible negative conductor are also provided making this new forge and outfit complete.

The smith seizes the piece of iron he wishes to manipulate with the insulated tongs and plunges it into the sour water which begins to boil and bubble the instant it comes in contact with the iron which, in a remarkably short space of time, turns to a red and then to a white heat ready for the work of the smith.

So rapidly is the heating done that the water and the portion of the iron not immersed in the water, is but slightly warmed.

The principle involved in this process is the same as in incandescent electric light. Resistance produces the light and heat. It is said that enormous heat can be produced by this method, much greater than is necessary to extract the iron from the most refractory ores.

Like all, or nearly all, of the late practical applications of electricity, this discovery will no doubt lead to marvelous results in the perfect and rapid handling of heavy iron and steel plates and bars that have to be hammered and welded; and more valuable still for tempering purposes as the required heat for the immersed portion can be quickly obtained while the remaining portion is kept comparatively cool, which cannot be done by present methods. By electricity we live and move, and by electricity some of us die.

Electric Fishes.

The fishes known to possess electrical organs number about fifty species, but only in five or six have these organs been carefully studied, says *Electricity*. The fishes are not confined to one class or group, and inhabit both fresh and salt water. The best known are various species of torpedo (belonging to the skate family), which exists in the Mediterranean and Adriatic seas; the gymnotus, an eel of the lagoons in the Orinoco region of South America; the malapterurus, or thunderer fish of the Arahis, which is found in the Nile and other African rivers; and various species of skates of the seas of northern Europe. The electrical organs belong to two distinct types, that of the torpedo, gymnotus and skate being closely related in structure to the mussel, while that of the thunderer fish has a greater resemblance to a secreting gland. Both types are built up of a vast number—lately estimated by Ewart at as many as 250,000 in a torpedo—of minute elements, each supplied with a nerve fibre.

Electric Launches in Venice.

A scheme is afoot for introducing electric launches on the canals in Venice. The Electric Launch and Navigation Company, which supplied the electric launches at the Chicago Exhibition, is said to have disposed of a number of launches to a company, which will put them in service on the Venice canals. The launch is not picturesque and there is no glamour of richness about it; but it will probably do away with the gondola, as cabs and omnibuses did away with Sedan chairs,

Useful Information.

The Time Without a Watch.

Actual and repeated experiments have shown, says *Tid-Bits*, that the nearest hour of the day or night may be ascertained in the following curious way:

Make a small running loop in a piece of sewing thread about a foot in length, place a shilling [a quarter] in this loop, see that the coin is accurately bisected by the thread, and then draw the loop tight up, so that the shilling is firmly slung at one end of the thread. Put on a solid table a glass tumbler with a fairly wide mouth. Rest your right elbow on the table in a firm and easy position so as to avoid any shakiness in your hand, hold the other end of the thread between your first finger and the "ball" of the thumb (i. e., the fleshy top joint of the thumb), so that the thumb nail is undermost and a few inches above the middle of the mouth of the glass.

Now, if you keep your hand quite steady, the movement of the coin (which is hanging inside the tumbler), will become less and less until the shilling is motionless. Then, in half a minute or so, a very slight and regular vibration will commence, the coin oscillating from side to side like a pendulum, and gradually increasing the length of movement until it gently strikes the side of the glass. The strike goes on in the most regular and automatic way—first on one side of the glass and then on the other, until, say, eight strokes have been struck; the vibrations of the coin then diminish in length until the suspended shilling again becomes motionless and hangs in the middle of the tumbler. You look at your watch and find that 8 o'clock is the nearest hour.

I have tried this over and over again, deliberately setting about the experiment without bias or in any intention of influencing the swing of the coin, and also being ignorant of the time, and when my hand has been steady the right time has invariably been struck.

There is something very curious about this phenomenon. Whether the thread is influenced by the pulse in the "ball" of the thumb, or whether there is some unconscious transference of "intention" from the brain to the thread, I do not know; but in any case, the matter is sufficiently interesting to be worthy of a critical test by persons who will carefully and without bias carry out this singular experiment of telling the time.

The Silk-Spinning Spider.

The silk spider of Madagascar forms the subject of an interesting article in *Die Natur*, by Dr. Karl Muller. Its native name is Halabe, meaning great spider. This Halabe, or *Nephila Madagascariensis*, spins threads of a golden color and strong enough, according to Maindron, to hang a cork helmet by. The female spider may attain a length of 15 cm., while the male does not exceed 3 cm. A single female individual, at the breeding season, gave M. Camboue, a French missionary, some 3000 m. of a fine silken thread during a period of about 27 days. The thread was examined with a view to creating a new industry. Specimens tested at a temperature of 17° C. showed an elongation of 12.48 per cent under a weight of 3.27 gr. Small textures woven of these threads are actually used by the natives for fastening flowers on sunshades and for other purposes.

To Beat the Ferris Wheel.

"The Gigantic Wheel," to be erected at Earl's Court, will, says *Invention*, be 50 feet larger than the great Ferris Wheel at the World's Fair, Chicago, its summit being 300 feet above the ground. It will be fitted with 40 cars, each holding 40 persons, and will

revolve at a very slow speed, about equal to the second hand of a watch. The round trip will occupy 20 minutes, with five stoppages, there being landing stage accommodation for filling and emptying eight cars at the same time. The cars will be luxurious. There will be novel opportunities for observation and for enjoying tea parties in the air.

To Measure a Room for Wall Paper.

To determine the number of rolls of paper to cover the walls of a room, measure the circumference, from which deduct the widths of doors and windows and divide the remainder by 3.

Example.—Let us suppose a room 12x16 feet, which has two doors and two windows, which average 4 feet wide:

$$\begin{array}{r} 12 \times 12 \times 16 \times 16 \text{ equal } 56, \text{ circumference.} \\ 4 \times 4 \text{ equal } 16, \text{ doors and windows,} \\ \hline 56 \\ -16 \\ \hline 40 \\ \hline 13\frac{1}{3}, \text{ or say } 14 \text{ rolls.} \end{array}$$

This rule is calculated for a room of not less than 10 or more than 12 feet in height. For a room under 10 feet high, having a frieze, say of six inches, we will proceed as before with the measurement of the room, deducting the widths of the doors and windows. But in this case multiply the remainder by two and divide by 15; for this reason, that we can cut five lengths out of a double roll, which, placed side by side on the wall, cover a space 7 feet 6 inches from the ceiling, and instead of multiplying by 7 feet 6 inches we multiply both by 2.

Example.—Take a room 14x14, with two doors and windows:

$$\begin{array}{r} \text{Circumference of room} \dots\dots\dots 56 \\ \text{Less for doors and windows} \dots\dots\dots 12 \\ \hline 44 \\ \hline 2 \\ \hline 15\frac{1}{3} \end{array}$$

Say 6 double rolls, or 12 pieces. Of course if a dado is required its width will determine how much paper will have to be deducted. — The Carpet and Upholstery Trade Review.

Soylla and Charybdis

The whirlpool of Scylla and Charybdis are situated in the Strait of Messina, between Sicily and Italian Apulia, and although dangerous to the mariner of the ancient world, are not very formidable in the present day. The whirlpool of Scylla lies at the base of the cliffs on which stands the village of Scylla. The circling waters have worn the cliffs into caves, which in heavy seas emit sounds like the harking of a dog. Charybdis is near the port of Messina, nine sea miles from Scylla, and, according to Signor Spallanzani, is 500 feet deep. The old danger of sailing between them has recently been explained by M. Keller, an engineer, who shows that the currents in the strait depend both on the tide and wind. The currents are strong because the tide is low in the Ionian sea when it is high in the Tyrrhenian sea and vice versa, and whirlpools, more or less energetic, are formed at various points of the strait. When the wind is from the south-east the waters pour from the Ionian sea into the strait and form whirlpools north of the port of Messina, and also near Faro, where ships at anchor are sometimes carried out to sea and borne by the current on the rocks of Calahria, toward the point of Pezzo, a little further off than Scylla. It is probable, therefore, the ancients meant by Charybdis the casual whirlpools near the port of Messina, and by Scylla those at Point Pezzo. Between these two points the currents are extremely rapid, strong and variable. The danger is really serious for sailing vessels, which were all the ancients had, and an experienced pilot might, in avoiding Charybdis, find himself in Scylla.—London Globe,

Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Patent Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and drawings free.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen.

First, the flanges or edges of our belt stand at an acute angle inrolling toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vibration and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

CHEMICAL LABORATORY,

524 SACRAMENTO STREET, - - - SAN FRANCISCO, CAL.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assay; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Residue; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1889. Price \$1. postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—PRICE \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion; Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhard's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new original and exact, as is also one of the processes for Zinc.

The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is replaced by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

GLADSTONE MINING COMPANY, C. J. Clark, M. E. Gen'l. Supt. FRENCH GULCH, Shasta Co., Cal., Dec 12, 1891.
 MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIR: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the Frues in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to mention. In order to give an idea of the work they are doing here I will state that the ore has varied monthly from \$5 to \$20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six foot Frue Vanner too highly, and it is the only table that I would have in my mill.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

OLD MINE TO BE OPENED.—*Record*, Mar. 1: The report is current and seems to be well founded, that an old, well-known mine is to be opened here this spring on an extensive scale. New men with abundant capital and large mining experience will assume control of the undertaking; in fact, it is said they belong to the old Comstock crowd who, in time past, made things hum in that historic camp. The same parties are said to be negotiating for still another mining property in this immediate vicinity.

There is every reason to believe that a great mining boom is in store for Sutter Creek district. While others were growling and accomplishing nothing, a few of our citizens have succeeded in interesting capitalists in various enterprises that will, when consummated, make Sutter Creek the most prosperous town in the county.

A FAVORABLE INDICATION.—*Record*: At the South Eureka mine the prospecting drifts and crosscuts on the 800-foot level are still being extended. So far no permanent body of ore in paying quantity has been developed. This week, however, a strong stream of water was encountered while the men were drilling in the east north crosscut, 180 feet from the main shaft. When the drill was withdrawn the water was thrown out by the pressure a distance of 30 feet. The flow was so great that for a time it required the full power of the pump to handle it. Old miners look upon this as a very favorable indication and seem to think there is a large body of ore near at hand.

THE WILDMAN MINE.—*Record*: At the Wildman mine, on both the new 1200 and 1300-foot levels, at a distance of 55 feet south of the main shaft, a heavy body of quartz has been struck, the ledge being eight or ten feet in width. The rock in the face is of low grade, but a portion of it looks promising and there is strong hope that, as the drift is extended, it may develop into a handsome-paying body of ore. After an idleness of three months the mill, with its 30 stamps, began pounding away on rock Wednesday night.

THE HECTOR MILL RUNNING.—*Record*: The Hector (formerly the Mahoney) mill started up 20 stamps on Wednesday, on rock taken out by Messrs. Campbell and Bean. They now have about 250 tons in the bins and are extracting, with three men, some 20 tons per day, so that the 20 stamps are likely to be kept busy for some time. They are working under a tribute arrangement and are making good wages, so we are informed.

Butte.

THE BEEHIVE MILL.—*New Era*, Mar. 1: G. W. Davies has returned from Mt. Hope, where he has been doing the mason work for the Beehive mill. He reports having finished his job, and that the work on the mill is being pushed with all possible speed. He is unable to fix upon a date when the mill will be completed, as bad weather may delay the time, but he thought that in four weeks the mill would be dropping its stamps. He says the mill is very substantially built, and when completed will contain all the latest improvements for saving gold.

Colorado capitalists have bonded the quartz ledge recently discovered by S. H. Hurley, near his hotel, at Hurleton.

The Burroughs Company is making arrangements to put a stamp mill upon their ledge on McCabe's creek. They have not decided whether to build a five or ten-stamp mill at present, but as the ledge is quite large, it will probably be that a ten-stamp mill will be decided upon.

ELECTRIC PLANT.—*Oroville Register*: Major Frank McLaughlin, general superintendent of the Banner mining property, received this week 70,000 pounds of freight, which included an immense electric plant for running the Banner mill and hoisting works, for lighting the mine and for furnishing light and power in Oroville. The plant will be located at the foot of Table Mountain, where the great ditch of the Thermalito Company has a fall of 142 feet. The water will be used to develop the electrical power, yet will not be lost, but will be brought on for irrigation purposes as in the past.

Del Norte.

FOR BEACH MINING.—*Del Norte Record*: Another gold-saving machine will be put up on our beach soon. The parties who have a new process are here and expect a machine and engine soon, when they will endeavor to extract the fine particles of gold from the rich black sand of our beaches. Numerous inventions have been tried, but so far without success, yet it seems reasonable that some day the right machine will be produced, and this latest invention may be the one. A late edition of the *MINING AND SCIENTIFIC PRESS* contained an article on a new gold-saving machine and the one that is to be set up here is probably the same. An extensive plant was brought here last spring for extracting magnetic iron and gold from the sand, and put up a few miles below town, but for some reason was never put in operation, but may be before long.

Calaveras.

THE NORTH STAR HYDRAULIC.—*Chronicle*, March 3: Monday last we paid a visit to the North Star Hydraulic, which is situated in Happy valley, about a mile from this place. The work of fitting up the claim, which was done under the supervision of C. M. Burleson, Esq., of this place, was commenced the 15th of

last November. There was 3200 feet of a two-foot flume put in, a fine office and a blacksmith shop erected, and in fact everything in and around the mine put up in first-class working shape. About twenty days ago water was turned on, since which operations have been going on steadily. The water for hydraulic purposes is taken from the Mokelumne and Campo Seco canal, under a 200-foot pressure; 300 inches of water are used, which is conveyed to the mine through an 11-inch pipe and directed against the bank through a 4-inch nozzle. A large derrick has been erected in the mine for the purpose of banding the rocks, and a power house, some distance from the mine, is now in process of construction. Operations at the mine, which are being prosecuted night and day, are under the supervision of J. K. Carpenter, Esq., and the working force consists of twelve men. The gravel bank prospects well and all indications are that when the cleanup is made it will repay the owners for all outlay made.

El Dorado.

FOUND GOLD.—*Republican*: J. C. Murphy of Kelsey has been finding some coarse gold near that place recently. Two pieces that have been exhibited weigh about \$125. One is almost pure gold and nearly round. The other is about one half quartz and oblong. They are from pocket seams but have been somewhat worn by water and debris.

The Esperanza mine near Garden valley has been reopened and the water pumped out down to the 190 foot level. Some of the rock will be taken out and crushed at the mill on the Lone Jack mine. The Esperanza is about a mile south of the Taylor mine and on the same general formation, so there is a good prospect that it may develop into an equally valuable property under good management and the requisite capital.

Kern.

RAIN IN THE GOLEA FIELDS.—A business man who had been all over the mining camps at Redrock, Goler and Summit a few days ago, reports to the Los Angeles *Herald* as follows: A good deal of rain has fallen the past two weeks and the ground in all the camps is soaked. In consequence of this nearly all the miners are idle at present. The gold is taken out by the dry-washing process, which can be done only when the dirt is in a dry, powdery condition. Most of the claims yet worked are in shallow ground, which even moderate rainfall wets to bedrock. A few claims are in ground where bedrock is ten feet or more below the surface. In these claims dry dirt is found, and there miners have been working without any interruption by rain. In all these claims men are making good pay. The visitor who makes this report says he learned that at Redrock, Goler and Summit there are men earning from \$4 to \$10 per day. It will take a few weeks of dry weather to put the ground in condition to push work as it was before the late rains. San Francisco parties are negotiating for the purchase of most of the claims at Redrock.

BOUGHT A MINE.—*Bakersfield Californian*:—The Talc gold mine was recently purchased by George W. King for himself and other Denver capitalists. It lies about two and one-half miles northeast of Woody Postoffice and is a promising gold property. The mines in that locality have been worked from an early date and have yielded a great deal of very rich quartz.

Mono.

ON UNIVERSITY ORE.—*Bodie Miner*: The Miners' mill is now running on ore from the old University mine. There was something over 100 tons of ore at the mill when operations were begun, and when the roads get in condition Dick Leale will commence hauling more.

Nevada.

MINING SURVEY.—*Telegraph*: On Monday a survey of the Granite Hill mine was completed and all the outlines of the ground will soon be outlined on a map. Not only has a survey of the mine been made, but also a survey for a mill site as the company intends at a very early day to erect a mill upon its property. The prospects at the Granite Hill justify any outlay which mining men choose to make.

STRUCK THE LEDGE.—*Transcript*, Feb. 27: John Campbell and son of Piety Hill have struck a quartz ledge in their residence lot, from which a crushing of rock has been taken.

Teams are hauling quartz from the Reward mine to the Nevada county mill to be crushed. Underground work at this mine was recently suspended, but we learn it is only temporary and that the shaft is soon to be sunk deeper.

The Grant mine at Canada Hill continues to yield fine quartz and the ledge is looking well. Messrs. Veal and Mosby, the lessees, are making the mine pay.

Ellison, Tremaine and Chappell expect to strike rich gravel soon in their claim on Selby hill. They have been working a long time and indications are that the main channel which they have been running for is near at hand.

PAID BRO.—*Union*: Three or four loads of ore from the Rose Hill mine, owned by Richard Lawrey, have just been crushed at Gauthier's mill. The yield was \$65 per load, which is very satisfactory indeed.

THE DELHI MINE.—*Transcript*: The Delhi Mining Company has been reorganized and, as now constituted, will soon begin work at the mine on an extensive scale. All the necessary machinery will be procured with which to open up and develop the mine on a larger scale than ever before, and a big crew of men will be employed. Work will begin next week. Chris Mallon, who has been superintendent of the Delhi so long, will be superintendent under the new company. Messrs. McMurray, Hamilton and Love, the principal owners, were here last week and arranged for resuming work on the mine which, it is believed, still contains a

vast amount of hidden treasure within its depths, and will be found to be as rich, if not richer, than ever before.

RICH STRIKE AT THE ODIN.—*Transcript*, Mar. 5: The most important strike ever made in the Odin gravel mine occurred on Saturday last. Some time ago the miners came upon an ancient waterfall, 17 feet in height. After drifting through 14 feet of sand a fine body of rich gravel was encountered Saturday, some of the prospects from which went as high as \$2 to the pan. This strike is very encouraging to the owners of the Odin, and corroborates the theory held by Superintendent Hesse that there must be an extensive body of gravel in the company's ground. Its proximity to the old Nebraska mine warrants the belief that much of the gravel will prove to be very rich.

BIO PROPOSITION.—*Herald*: There is a big mining proposition under way in Washington district which angers well for that section. Henry Kohler, the pioneer merchant, and certain others, have a claim on Canyon creek, which is on the same extension as the Yuba, Lindsey, California and others known to be good mines. The prospects are that considerable work will be done there this year.

THE TELEGRAPH MINE SOLD.—*Grass Valley Union*: Jacob Weissbein has purchased the Telegraph mine, which adjoins the W. Y. O. D. on the north, from James Glasson. The mine has been worked to but a superficial depth, but its favorable location makes the property valuable.

FOR DRIFT MINES.—*Herald*: A promising section of this county is Moore's Flat and Graniteville. It is full of mineral, and what has been taken out seems to be but a fraction of what is still in the ground. There was considerable activity in that neighborhood last summer, and the indications are that far more extensive operations will be seen next summer.

The late D. R. McKillican's property, for one, is to be worked if reports are true. The big gravel claim near Moore's Flat has been purchased by a company of New Yorkers, and a drift will be run into it from the Moore's Flat side. J. H. Cunard of Bloomfield has been engaged to superintend the operations, and it is said to say no better man could have been secured.

THE JACK RABBIT.—*Transcript*: J. B. Storch, superintendent of the Jack Rabbit mine, has issued a report on the condition and prospects of the mine. We make the following extracts: "Leave the theoretical consequences aside, which, according to the formation the Jack Rabbit mine is located on, are extremely encouraging, and judging after the practical experience on the developments from the numerous prospect holes, cuts and drifts on the surface, down to the lower and finally to the lowest level, 183 feet underground, you will observe a gradual improving of the quartz stringers the deeper you come, increasing in color and width. You will find that a number of minute quartz stringers are constantly uniting to one ribbon of considerable size, and you will find that the white, dead crystalline, sugary color changes into gray metallic colors, finally beginning to be uniformly infiltrated with gold and other metallic gold and silver-bearing sulphurets, etc. And you will find all over the Grass Valley district that exactly the same indications guided the miners to a rich strike in all the dividend-paying mines. Now come to a common-sense conclusion. Taking everything into consideration, what theory, practice and local experience teach, you will come to the conclusion that the Jack Rabbit mine is entitled to the same expectations as any other well-paying mine in the Grass Valley district, when the line of the settled formation will be reached—therefore, the plan of operations has to be changed."

WILL ERECT PUMPING MACHINERY.—*Transcript* March 3: Fairweather & Co., who are operating a quartz mine near North Bloomfield, are taking out fine rock and their prospects are highly encouraging. The shaft is now below water level and it is necessary to have a pump to handle the water. The owners are arranging to put in the needed machinery.

Riverside.

AT THE GOOD HOPE.—*Riverside Enterprise*: The grading for the new mill to be erected on the Good Hope mine has been completed and lively times may be looked for there before long. It is stated on good authority that the new mine will employ at least 300 men when in full operation. J. K. Estep, a representative of the Union Iron Works of San Francisco, is at the Good Hope ready to begin the erection of a new mill, which is being built by the iron works and which is expected to arrive soon. The owners of the Snow Bird mine, which is located near Winchester, are considering the question of the erection of a stamp mill. Report comes that both the Rose mine and the Christie mine, which latter is an extension of the Rose, are showing up in good shape of late. It is said the Rose is paying handsomely now, although the owners, who live in this city, do not talk much of the mine.

San Bernardino.

AT THE CAMPBELL MILL.—*Shaft*, March 2: Mr. Stanley, Mr. Campbell's right-hand man, and Chief of Construction Rich, say that stamps will commence dropping in the Campbell mill next Monday.

At the Boomerang the main shaft is now about 50 feet below the lower level, and is being sunk rapidly by three shifts of good men. The vein is looking splendidly all the way down, and considerable water is being found. Although Mr. Campbell has not stated his intentions in the matter, it is supposed that he will continue to sink his shaft as fast as it can be done until the 500-foot level is reached, and perhaps farther.

The mill at the Bronze has reached that point

where a good deal of time can be put in without any apparent result from hour to hour. But it is nearly ready for business, and the placing of the machinery will soon be done. It is very likely that by March 10th ore will be worked in this mill. Everything about it will be first-class, and it is a foregone conclusion that the best of results will attend the working of the ore.

At the Bronze the chief feature during the past week was the striking of a quality of ore that runs much higher than that which has been taken out, rich though it has been. This strike was made at the very lowest point in the vein, and although the winze has been sunk still farther the quality remains the same. The character of the rock is not changed, it still remaining a pure quartz, just as it has been for a long time. This new ore is very rich and the ledge is of good width.

The pumping of the water out of the St. George still continues, and will soon be done. Progress is retarded by the necessity of re-timbering the shaft, the work being poorly done before. An interesting event in the work was the uncovering of a seven-foot vein at the 250-foot level by the falling away of the wall. This probably insures the sale of the mine to Mr. Schofield's company; and, if the purchase is made, it will be worked for all there is in it, which is just what we desire to see. That property is too valuable to lie idle.

NEW GLADSTONE CAMP.—*Needles Eye*: The rich strike made by Patrick Dwyre and James Walker, 26 miles west of Fenner, has aroused considerable interest in Needles. Last week Judge West, Pat Flynn and others from this point, giving it the appropriate title of Gladstone. On Monday F. C. Robie, Ben Harshberger and William Hunt left for the field. They are seeking mineral locations. The strike is unquestionably a phenomenal one. The ore from one of the claims runs high in gold and silver. The ledges run from a few inches to two feet in width, and are rich in free gold. Mr. Dwyre has made five trips to the place before, but has always been unable to find the ledges, as they were covered with dirt. The place is 26 miles west of Fenner, 11 miles southwest of Providence, and about 50 miles south of Vanderbilt. On last Saturday a good strike was made by Charles Lingo and J. L. Sullivan, 10 miles south of town. They brought in some very rich pieces of float, and on Monday returned to the scene. They are confident that they have struck it rich.

Sierra.

RICH ROCK.—*Downieville Messenger*: A piece of very rich rock the other day was taken from the bottom of the shaft at the Gold Bluff mine. The rock is of the ribbon variety and fairly "lousy" in free gold and rich sulphurets. All parts of the mine are showing up much better than ever. The several ledges are widening out and the main ledge, on which the shaft is sunk, is growing richer as it goes down.

Shasta.

SUCCESS AT BULLYCHOOP.—*Courier*: Mr. R. G. Hart says that tunnel five on the Texas and Georgia in Old Diggings struck the chute 150 feet below tunnel four on the 22d nit. The vein at this depth is a whopper, and the ore mills first-rate. He is now arranging to add a leaching and chlorinating plant to his mill on this mine, and has ordered the brick and mortar for the roasting furnace of Holt & Gregg. This addition will be the same and of like capacity to that now successfully working at Bullychoop. In speaking of Bullychoop, he says the reduction plant is now successfully working the refractory ore of that great mine. A Frieburg graduate is now handling the chlorinating plant there and is working the ore up to a high percent. Bullychoop from now on will yield big dividends. The roasting furnace (a reverberatory) has a capacity of five tons, but they are putting through but three and a half tons at present. This is because the furnacemen are not yet sufficiently trained to run it to its full capacity. However, the plant is now yielding a net profit of \$125 a day. Mr. Hart says the cost of mining, milling and chlorinating at Bullychoop now costs just \$3.50 per ton of raw ore. This is an important fact for mine-owners of Shasta to make a note of. The milling and concentrating plant at Bullychoop handles 30 tons per day, and the whole plant represents an expenditure of about \$20,000. The mine is such a large producer of good ore that the capacity of the plant will probably be double in another year.

Trinity.

FOUR-FOOT LEDGE.—*Trinity Journal*: It is reported that a four-foot ledge of good rock was struck in the Yellowstone mine, East Fork district, this week.

Siskiyou.

ABUNDANT WATER.—*Yreka Journal*, Feb. 28: The miners at Hawkinsville are pushing their mining operations vigorously, with an abundance of water to keep sluicing until late in the summer. At present there is too much water, but it is used to good advantage in ground sluicing.

The hydraulic mines in all sections of the county are now being worked full-handed, with plenty of water to keep all the giants supplied, besides running the hydraulic elevators and other apparatus requiring a great body of water.

All the high and dry gulch diggings near the summits of the high hills are beginning to be well supplied with water since warm weather set in this week, and there is a great amount of snow high up to keep the supply plentiful for quite a long time, much longer than usual.

The cold weather of the past few weeks, though not severe, was sufficient to stop the flow of water in all the placer mining claims, yet had the effect of hardening the snow to make it melt more gradually for general benefit when the weather moderated to warm, spring-

like temperature. This is better for miuera than warm rains and warm days to dissolve the snows of the mountains and gulches with a rush, only to be wasted in causing heavy freshets so common in California.

NEVADA.

Washoe District.

OFFICIAL COMSTOCK NEWS.—The following official statements have been received from Comstock mines and filed at the local offices:

Con. California and Virginia—1650 level.—From the drift run north from the foot of this apraise on the sill floor of this level, at a point 190 feet in from its mouth, a west crosscut has been advanced 19 feet, passing in porphyry and quartz of low assay value. The crosscut running east from the drift run north from the east crosscut No. 1 from the north drift from the winze (down 52 feet) has been extended 23 feet; total length, 68 feet; face in porphyry and quartz of a low assay value. In working upward, near the mouth of the east crosscut, we have extracted some ore. The ore from this point with that extracted in our workings in the vicinity of the winze—down 20 feet—amounted to 25 tons, assaying \$50.35 per ton. Have shipped to the Morgan mill 166 tons and 1270 pounds of ore, the assay value of which, per car samples, was \$31.56 per ton. The assay value, per battery samples, of the ore worked at the mill during the week (30 tons) was \$28.55 per ton. The crosscut No. 1 started from the southwest drift (the Rule drift) from the 1000-foot station of the Consolidated Virginia shaft, at a point 343 feet south of the shaft station, has been extended 42 feet, passing through porphyry, clay and quartz; total length, 50 feet; face in porphyry formation. At a point ten feet south from the east crosscut, on the east side of the drift, we have cut out an opening from which we are preparing to carry up our apraise. This opening is the size of two square sets of timbers, or 12 feet along the drift and 6 feet to the east. In the northerly part of the opening some streaks and bunches of ore were exposed which extended eastward and upward. Samples taken from the top of the south half of the opening gave an assay value of \$34 to the ton, and samples from the sill floor of \$14 per ton. The ore which has been saved from this opening shows an average value of \$20.50 per ton. At a point in this southwest drift, 527 feet from the shaft station, or 117 feet north from the Best & Belcher connection, an east crosscut (No. 2) has been started.

In the Ophir mine, on the 1465 level, the north drift from the west drift is in 176 feet and is cutting porphyry, clay and quartz of low assay. An advance of 114 feet has been made during the week in reopening and repairing the Central tunnel, making the total length of the drift reopened from its mouth 800 feet. Have continued (jointly with the Mexican Company) the work of making repairs to the main shaft. In the Mexican mine, on the 1465 level, the west crosscut from the south drift from the apraise 40 feet above the sill floor is in 261 feet, and the face is in porphyry and quartz of low assay. Near the mouth of this crosscut an apraise has been carried up 16 feet in porphyry and quartz of low assay value. In the Andes mine, on the 420 level, west crosscut No. 3 was extended 16 feet; total length, 54 feet. Formation quartz, with some porphyry. In the Best & Belcher mine, on the 900 level, the east crosscut on the north boundary has been extended 16 feet; total length, 174 feet; face in porphyry. They are also doing some repairing on the 400 and 900 levels.

In the Gould & Curry mine, on the 200 level, west crosscut No. 5 in the northwest drift, 432 feet from the main west drift, has been extended 12 feet; total length, 919 feet; face in hard porphyry. In the Hale & Norcross mine, on the 1300 level, they have been timbering the greater portion of the week. Extracted from winze below this level six cars of ore assaying \$17.99 per ton. In the Kentuck Con. mine, on the 1100 level, the south drift from the top of the apraise above the north crosscut is in 37 feet; face in fair-grade ore. They have started a raise at this point to connect with the 1035 level for better ventilation. The west crosscut from the south drift near the south line is in 49 feet and continues in low-grade ore. They will start work on the 1200 level on the 5th inst. In the Alta mine they advanced the apraise 16 feet; total height, 73 feet; face in quartz and porphyry carrying low assays. They have extracted about eight tons of ore from south etope, the average value of which according to car samples is \$42 per ton.

THE RULE DRIFT.—*Virginia Chronicle*, March 6: There are three months yet ere the Rule contract with the Con. Virginia Company will expire, and several hundred feet of ground to explore; yet, from the hear feeling evinced at present, it would seem bonanzas are expected to pop out without being sought, and if they do not there is something wrong. There are four men working on a shift in the Rule drift at present—two in the apraise 343 south of the shaft, and two in the east crosscut 527 feet south of the same point—and the advancement of operations is consequently slow. Mr. Rule, who favors more rapid work, hopes that the Con. Virginia Company will increase the laboring force after awhile and prosecute explorations more vigorously. The main drift is through heavy ground, and requires attention also to keep it open. The crosscut above named is at present about 20 feet out. It will probably be 100 feet or more in length when it reaches the east wall of the ledge. It is running in favorable ground, and has many chances of developing an ore body. The apraise still has ore streaks in the top which may run into a big deposit at any moment. There is plenty of room for an ore body between the shaft and the Best & Belcher winze, which are 644 feet apart, and Mr. Rule is just as certain as ever of finding ore. Thus far the workings in the ledge are all on the east side of the Rule

drift. The west side offers a field of some proportions also, which will probably be tackled in due time. The prospecting operations will necessarily seem slower than the driving of the main drift, owing to the division of laborers among the different workings.

Silver Star District.

A GOON GOLD CAMP.—*Douglass cor.* Hawthorne *Bulletin*: There are two camps here. One is on the west slope of Robb's Ridge, facing the Garfield mill, and the other is on the east slope.

On the west side are located the Dunlap & Truman mine, running easterly and westerly. They are running a tunnel on the ledge and are in 50 feet, showing a ledge from two to six feet wide. They had no prospect of gold when they started the tunnel, but now the workings show from \$5 to \$25 per ton. Mr. Dunlap informs me that he can transport his ore to the Garfield mill for \$1 per ton.

The next claim, adjoining this on the north and running parallel to it, is the Deluvia, owned by Frank Pedrazzi. There is a tunnel run on the coners of the ledge 25 feet; average size of ledge, two feet. There is on the dump sacked for shipment to Hawthorne seven tons of ore that is estimated \$30 per ton. This ore will be shipped to get a mill test of the ore.

Next on the north is the Judy, owned by Flemming & Grassie. A tunnel in ten feet exposed the ledge and they are now sinking an incline on it. There is a 20-inch vein of fine quartz. On the dump is seven to ten tons, which assays \$40.

The two extensions of this mine on the north west are owned by Bowen & Fanr. They are the Pinte and Toyabe. There has been but little work done on these two claims, but the ledge crops out and shows a two-foot ledge. Mr. Bowen informs me that the croppings will horn from \$5 to \$25.

The Fottler mine is owned by Douglass & Co., and is located next to the Deluvia. This mine has a cut run in showing a three-foot ledge that the owners say will horn \$20. The ledge crops out full length of claim.

Next east is the Duke, owned by Douglass & Co. Incline 20 feet follows 18 inches of \$5 to \$20 ore.

Next is the Excitement, owned by Douglass & Co. No work has been done, but a strong ledge runs clear through it.

Adjoining this is the New Party, owned by Douglass & Co. Incline 12 feet, showing 18 inches \$20 ore.

Next east is the Hard Scrabble, or Brown mine, owned by Ed Brown. This is the chief of the camp at present and is a wonderful deposit of ore. It is sunk on to a depth of about 30 feet, showing a ledge of five feet of ore. There is on the dump some 40 tons of ore. About 200 sacks of this ore was sampled and assayed by W. J. Douglass, assayer for the Mt. Diablo Co., and went \$204 per ton. The second-class ore is estimated at \$30 per ton.

East of this A. W. Curtiss and Robert Webster have claims which prospect well.

Another good property is the Orphan Boy, running parallel to the Duke. The ledge has been opened 30 feet deep by tunnel, showing three feet of decomposed ore, average dump samples of which go \$42.

These are only a few of the claims located.

The weather has been rough for the past ten days. A good deal of snow has fallen, preventing prospecting to a great extent, but now the snow is going off and if it continues fair prospectors will soon be able to go into the hills.

Devil's Gate District.

GOON ORE.—*Territorial Enterprise*: During February the Oest mine, in Silver City, produced 100 tons of ore, the average value of which did not fall far below \$75 a ton in gold. F. Bierke, owner of one-half of the property, showed a sample of the ore taken from a streak or pocket in the mine which was an almost solid mass of wire gold. Pockets of this character have frequently been developed in the mine in the past twelve months, a few sacks of ore from which swelled the monthly output from the property up in the thousands.

The Zedig tunnel is showing ore of fair quality at several points, which will be extracted when the tunnel connects with the workings of the Northern Belle and other locations in Devil's Gate District. The tunnel is being run for the purpose of draining the mines of that district at a depth of 200 feet below the present workings. The Oest mine shows a fine ore vein on the water level, and when the tunnel is completed it can be followed downward without incurring the expense of placing a costly pumping plant on that property. The Zedig tunnel will prove as valuable an outlet for water to the mines of that district as the Sutor tunnel is to the Comstock lode.

Colonel Quinn is extracting ore from the Hayward and the returns are very satisfactory, leaving a good margin above operating expenses. W. Naleigh and "Pap" Smith are saying nothing but are evidently sawing wood and the returns from their mining property in that district are encouraging. Numerous other mining locations there are steady producers of the yellow metal.

Kennedy District.

TESTING ORES.—*Silver State*: John Ross has been assaying and testing the ores of the camp for the last ten days. He finds everything satisfactory, and under his supervision the mill is being remodeled and will be ready to start up in a week or ten days, when it is hoped that it will be successful.

ARIZONA.

GOON GOLD MINE.—*Prescott Journal-Miner*: George Wickler and J. W. Barrington are developing their Silver Flake mine on Groom creek. The name of this property is a misnomer, as it is a gold-producing mine. The

ledge is good and strong and yields ore which goes \$30 per ton in gold.

Dan Hatz is making a success of his arrastra. He brought in several hundred dollars recently as the result of a partial clean-up. This property is well developed, and to a company or individual who would take hold of it, erect a 20-stamp mill and work the ore from it, the property could be made to pay handsome dividends.

Another good property in the Hassayampa district is the Dan O'Boyle group of mines. This property consists of ten claims, several of them being fairly well developed, sufficient to keep a 20-stamp mill at work reducing ore. This is a property, too, which offers tempting inducements for investment. A 20-stamp mill on this group could be made to pay for itself and the entire purchase price of the property within a few months.

Big Bug and Chaparral continue to keep up their reputations as producers of gold bullion and are enriching the owners of all mines that are being worked.

Daniel E. Keating, the well-known mining man, who formerly operated in Humburg district, has returned to Arizona as agent of the Storm Cloud Mining Company, and it is understood that operations will be commenced again soon on this property.

NO SHUT-DOWN.—*Tombstone Prospector*, Mar. 4: A rumor that the T. M. & M. Co. would dispend with all of the men working there has been indistinctly circulated for a week past. To-day was to have seen the formal shut-down, but it did not take place. But six men were let out at the North-west mine. At all the other mines the full complement of men is at work taking out good ore which is being shipped to the smelters. Although silver is low, this company is paying all expenses and a little better.
